ARTERIAL HYPERTENSION

CHAIRMAN'S ADDRESS

ROY W SCOTT, M D
CLEVELAND

Four years ago I presented a paper¹ before this section entitled "Hypertension a Century After Bright" in which the etiology and pathogenesis of clinical hypertension and, more specifically, so-called essential hypertension were considered in the light of recent experimental studies of Goldblatt and his associates. After surveying the evidence, both experimental and clinical, I advanced the following hypothesis concerning the interrelation between arteriosclerosis, hypertension and kidney disease.

Arterial and arteriolar sclerosis of the kidney vessels excite a renal humoral mechanism which produces an increased muscular tone in the peripheral arterioles and thus causes elevation in the systemic blood pressure.

This explanation of that most common type of protracted elevation in blood pressure, hitherto called primary or essential hypertension, was regarded by many as a bold step. Now, after four years, the position has suffered no major attacks; indeed, it appears better fortified by more recent experimental and clinical observations. However, there are still a few men in positions of authority who would keep the etiology of essential hypertension surrounded by obscurity and have us cling to the notion that the kidneys play no role in the genesis of this type of hypertension.

As there are few questions of more importance to the practitioner than hypertension, I will devote my chairman's address to the thesis that arterial hypertension and especially so-called essential hypertension, is of renal origin.

Obviously eliminated from this discussion is the occasional clinical case of arterial hypertension due to such endocrine disorders as dysfunction and tumors of the pituitary and adrenals, and to disorders of the nervous system such as tumors and psychogenic disturbances. That the endocrine glands may play a role in some clinical cases of essential hypertension is established, but it should be noted that the majority of hypertensive patients show neither clinical nor postmortem evidence

of disease of the endocrine organs. Because psychogenic factors often cause wide variations in blood pressure levels, it is assumed by some that the nervous system plays a major role in the pathogenesis of essential hypertension, but there is no evidence that disease of either the central nervous system or the vegetative nervous system is the cause of essential hypertension.

We are not concerned here with those cases of systolic hypertension usually found in elderly persons whose blood pressure may be persistently well above normal but who do not have a corresponding elevation in diastolic pressure. Such patients often survive to a ripe old age and post mortem exhibit widespread arteriosclerosis of the aorta and other large arteries.

In the consideration of a question about which opinions differ, it is often profitable to launch the discussion by reviewing such evidence as is accepted to be factual. For example, a hypertrophied heart without intrinsic heart disease is accepted as a reliable post-mortem evidence that, during life, arterial hypertension was present. Let us therefore examine carefully a large series of such heavy hearts. We shall find a few cases of cor pulmonale, a few cases of long-standing coronary arteriosclerosis, and an occasional example of such rare disorders as either Fiedler's myocarditis or idiopathic cardiac hypertrophy. Eliminating these we have an overwhelming percentage of our original cases in which a careful examination of the heart reveals no cause for the hypertrophy. But let us have a look at the kidneys! The correlation between cardiac hypertrophy and diseased kidneys is as striking today as it was in Bright's day, indeed more so, since our improved technical methods supply information, particularly regarding the intimate vasculature of the kidneys that was not available to Bright.

The correlation between diseased kidneys and cardiac hypertrophy without intrinsic heart disease led Bright more than a century ago to postulate the renal origin of hypertension. This conception was accepted and widely held until 1872, when Gull and Sutton impressed by the diffuse nature of vascular sclerosis, which they called "arterio-capillary fibrosis" assumed that "these changes are, or may be, independent of renal disease and that the renal changes in chronic Bright's disease with contracted kidneys when present, are but a part of the morbid condition."

Attention was thus focused on diffuse vascular disease as a primary pathologic entity while the renal vascular changes were regarded as secondary. The conclusions of Gull and Sutton were generally accepted.

Read before the Section on Practice of Medicine at the Ninety Third Annual Session of the American Medical Association Atlantic City N J June 11, 1942.

¹ Scott R W. Hypertension a Century After Bright. J A M A 111: 2460 (Dec 31) 1938. Only those references not contained in the paper cited are cited in the present address.

² Heretofore the kidney has not been regarded as an endocrine organ but its role as such is indicated by the recent observations in experimental hypertension.

and as a result there began a swing of the pendulum away from Bright's view regarding the renal origin of hypertension. As observations on patients with hypertension rarely showed impairment of renal function, there emerged about the turn of the century the modern concept of so-called essential hypertension, which has widened the breach still further—so far, indeed, that the kidney was thought to play no role whatever in this type of hypertension.

Now, with the proof afforded by Goldblatt, and many others who have confirmed his results, the renal origin of hypertension is firmly established and Bright after a hundred years stands vindicated.

Time does not permit a survey of the experimental work which entirely supports the modern conception that persistent arterial hypertension is due to the resistance imposed by widespread hypertonicity of the peripheral arterioles. That this peripheral hypertonus in man is not vasomotor in origin has been shown by the work of Prinzmetal and Wilson and by Pickering, whereas all observations bearing on the pathogenesis of experimental hypertension indicate that it is not of reflex but of humoral origin.

We may now return to our human material exhibiting cardiac hypertrophy. Let us consider first those showing obvious renal disease, because here is evidence for the existence of renal hypertension which even our most ardent opponents must and do accept. We shall see examples of chronic glomerulonephritis, polycystic disease, chronic pyelonephritis, severe amyloidosis, periarthritis nodosa of the renal vessels, congenital hypoplasia of one or both kidneys and an occasional case of adenomyosarcoma (Wilms's tumor) of the kidney. We shall also see examples of hypertension associated with obstruction of the urinary passages, such as hydronephrosis, prostatic enlargement and carcinoma of the uterus with ureteral obstruction. In addition to the foregoing evidence supporting the existence of purely renal hypertension, I may cite as further evidence the well known clinical observations of a prompt elevation of the blood pressure observed in a young patient with acute nephritis and in patients with embolism of the renal artery.

Since the work of Goldblatt shows that hypertension may result from constriction of the main renal artery, we shall look for and find a number of cases in which arteriosclerosis has narrowed one or both renal arteries. I saw a patient recently who several days before death developed a severe and unexplained hypertension. A postmortem examination revealed an ascending thrombosis of the aorta which had blocked both renal arteries.

The most striking example of all, proving the direct relation between the kidney and hypertension, is the fall of blood pressure following nephrectomy in a patient with unilateral renal disease.

In the face of such evidence it is clear that diseased kidneys exercise a direct control over the tonicity of the peripheral arterioles, which in turn regulates the systemic blood pressure.

"Very well," say the opponents, "we agree that hypertension accompanying obvious kidney disease is due to a renal mechanism, but what about those cases of protracted hypertension that neither have, nor develop, clinical evidence of renal disease?" Here we may pause to review briefly the origin of the modern concept of so-called essential hypertension.

After the sphygmomanometer came into general use about 1900 and clinical measurements of blood pressure

accumulated, the clinicians of the time sought a correlation between hypertension and clinical evidence of sclerotic changes in the arteries. Failing to find such a correlation, some assumed with von Bosch and with Huchard that the elevated blood pressure was a precursor of vascular disease. Others, notably Allbutt, believed that organic changes in the arterioles were not sufficiently widespread to cause persistent hypertension, which was thought to be due to a generalized vasoconstriction. Thus Allbutt explained the pathogenesis of hypertension but not the etiology. In other words, he did not determine the cause of generalized vasoconstriction, but the kidney was not seriously considered as playing a major role in the production of this type of hypertension.

A survey of the literature in the decade following 1900 reveals a widespread interest in the interrelation of hypertension, arteriosclerosis and renal disease, which culminated in four points of view. They were that: 1. Kidney disease was primary and caused both hypertension and arteriosclerosis. 2. Diffuse vascular disease was the cause of hypertension and the kidney played no role in the genesis of either hypertension or arteriosclerosis. Such renal vascular lesions as might occur were regarded as incidental and but a part of generalized vascular disease. 3. Hypertension was the cause of arteriosclerosis, as Huchard wrote, "Hypertension precedes by a longer or shorter time the evolution of the various diseases (arterial cardiopathies and nephritides) which are in themselves dependent on the vascular sclerosis." 4. Hypertension resulted from a generalized vasoconstriction of unknown origin but unrelated to either kidney disease or to vascular disease.

Conflicting as these views may now seem, it should be recalled that they were based on an incomplete knowledge of kidney disease, and it was not until 1904 that Jores and others recognized two types of scarred kidneys: the inflammatory and the arteriosclerotic, both of which had been confused since Bright. A great advance in the field was made in 1914 when Volhard and Fahr published their observations on the renal vascular lesions in hypertension. They showed that the kidneys of patients with essential hypertension exhibited more or less diffuse sclerosis of the smaller renal arteries and introduced the term "nephrosclerosis" to describe this condition. Although pathologists had no difficulty in verifying the observations of Volhard and Fahr, most clinicians, impressed by the great frequency of hypertension without clinically significant renal disease, assumed that the kidney played no role in this type of hypertension.

Thus there emerged the concept of primary or essential hypertension—a term which implies an obscure etiology of the hypertension and separates it from renal hypertension. In other words the term essential hypertension really means nonrenal hypertension of undetermined origin. From the German *essentielle Hypertonie*, first used by Frank, came the term essential hypertension, which has been used in this country for more than twenty years.

If, as some assume, the kidneys are not concerned in the pathogenesis of so-called essential hypertension, then it seems reasonable to suppose that the majority of cases would show no significant renal disease. But, as is well known they do show renal disease. Indeed, there are seasoned clinicians and pathologists who claim never to have seen a case of prolonged hypertension in which a careful postmortem examination did not reveal dis-

eased kidneys In 1928 Bell and Clawson, in a careful study of 420 cases of essential hypertension, found renal arterial disease within the parenchyma of the kidney in 97.4 per cent and sclerosis of the afferent glomerular arterioles in 89.4 per cent Fishberg reported renal arteriolar sclerosis in 100 per cent of a series of 72 cases of essential hypertension

More recently Moritz and Oldt, in a purely objective study of the arterioles from many parts of the body of 100 persons with and 100 persons without hypertension, found a high correlation between arteriolar disease and hypertension in one situation only, the kidneys In view of such evidence the question naturally arises Why has the renal origin of essential hypertension been questioned, and on what grounds were the kidneys removed from consideration?

The chief arguments were as follows 1 Protracted hypertension may exist without demonstrable impairment of renal excretory function 2 The great majority of patients with essential hypertension never develop renal insufficiency but die of heart failure or a cerebral vascular accident 3 Occasionally a patient with well defined hypertension is reported as showing no anatomic evidence of renal arteriolar disease

The fact that protracted hypertension occurs without demonstrable renal excretory insufficiency afforded the major support for the concept of essential or nonrenal hypertension Now that the experiments of Goldblatt and others have demonstrated the role of the kidney in producing hypertension that pronounced and persistent elevations in blood pressure may be produced in animals which exhibit no demonstrable evidence of renal excretory insufficiency, those who still adhere to the nonrenal conception of hypertension are deprived of their most cherished argument The hypertensive animal with the main renal arteries constricted, but without manifest renal excretory functional disease, is, as far as concerns the phenomenon of hypertension, the experimental counterpart of benign essential hypertension observed in man Even the clinical picture of malignant hypertension has been produced in the hypertensive animal by further narrowing of the renal arteries Such animals exhibit the changes observed in human malignant hypertension, i e papilledema, retinitis and protein retention with uremic death, and at postmortem show the same type of arteriolar necrosis as that seen in man³

Thus, by interference with the blood supply to the kidney the phenomenon of hypertension is reproduced in animals Here is the solution of a problem which has puzzled clinicians for decades, namely, hypertension clearly of renal origin both with and without demonstrable renal excretory insufficiency Those who believe that these animal observations do not apply to man must explain the close parallelism between experimental and clinical hypertension, both benign and malignant As far as a functional disturbance is concerned—and certainly hypertension is a manifestation of an altered function—there is no more striking similarity than that of experimental renal hypertension to clinical hypertension Rarely has the animal experimenter so faithfully reproduced a protracted alteration of function such as occurs in human hypertension

One other argument presented in defense of the nonrenal genesis of essential hypertension is that occasionally hypertensive patients are reported as showing post mortem no renal arteriolar sclerosis This observation carried more weight formerly than now, because prior to Goldblatt neither clinicians nor pathologists were aware of the fact that sclerotic narrowing of the main renal arteries caused hypertension All such cases were probably overlooked and classified as instances of essential hypertension without renal arteriolar disease

How frequently one finds significant sclerosis of the main renal arteries is shown by the recent observations of Blackman⁴ In a series of 50 cases of essential hypertension, he found pronounced stenosis of one or both renal arteries in 27, or 54 per cent Therefore unless the main renal artery is examined, as well as its branches within the kidney, the failure to find arteriolar lesions cannot be accepted as evidence against the renal origin of hypertension In any attempt to associate hypertension with renal arteriolar disease we should bear in mind that we are correlating an alteration of function with one of structure and that in such an equation there are unknowns, an important one of which is the quantitative relation between renal lesions and hypertension In other words, we do not know how widespread the renal vascular lesions must become in order to excite the mechanism responsible for hypertension This mechanism is induced in animals by narrowing one renal artery, it operates in human beings with unilateral renal disease and ceases, as is now well established, on the removal of the diseased kidney These facts indicate that a reduction of the blood flow to one half of the total kidney mass is sufficient to elevate the blood pressure but beyond that we have no knowledge of the quantitative relation that may exist between kidney disease and hypertension

The most impressive work on the incidence of renal arteriolar disease observed post mortem in patients with essential hypertension is that recently published by Bell⁵ who studied 1520 cases Although his findings afford a strong link in the chain of evidence supporting my thesis, Bell has interpreted his data in the opposite way I am constrained therefore to mention certain obvious limitations imposed by the nature of his observations on the relation of renal arteriosclerosis to hypertension

Those who are familiar with his work on the subject know that his use of the term "arteriole" refers to an afferent glomerular arteriole which supplies only one glomerulus Since there are about 1,250,000 afferent glomerular arterioles in each kidney the pathologist who examines one or two routine sections will see at most 10 preglomerular arterioles, or 1 in 125,000 If he was to examine one hundred sections he might then observe 1 in 12,500 preglomerular arterioles Obviously, then success in finding renal arteriolar lesions after examining a few sections of the kidney means in reality that virtually all the arterioles are involved whereas a failure to find them in even one hundred sections cannot be accepted as proof that no such lesions exist

I recently saw a patient with chronic hypertension who died of congestive heart failure The postmortem

3 Arteriolar necrosis is not observed in the kidneys of animals with clamped renal arteries This suggests that an increased intravascular pressure is an important factor in the production of arteriolar necrosis

4 Blackman S S Jr Arteriosclerosis and Partial Obstruction of Main Renal Arteries in Association with Essential Hypertension in Man *Bull Johns Hopkins Hosp* 65 333-375 (Nov) 1939

5 Bell E T Primary Hypertension Clinical and Pathological Study of 1520 Cases With Especial Reference to Renal Arteriosclerosis *Proc A Life Insur M Dir America* (1939) 26 269-293 1940

weight of the heart was 600 Gm, and it exhibited no evidence of intrinsic heart disease. As happens in some such cases, the kidneys were not remarkable grossly. Together they weighed 400 Gm, and the surfaces of both were smooth. From an examination of a single routine section of each kidney, our pathologist reported no renal arteriosclerosis and demonstrated the case as an example of essential hypertension without renal vascular disease. This negative finding was a challenge. The sections were carefully restudied and the sparsity of preglomerular arterioles was noted. After a thorough search only 2 seriously affected afferent glomerular arterioles were found. Then about one hundred sections of each kidney were examined and the existence of a widespread preglomerular arteriolar disease was established.

Turning now to Bell's paper, we find in a series of 1,520 cases 246 of hypertension of myocardial type—that is, cases in which the major symptoms were those of heart failure—and in these he was unable to find renal arteriolar lesions in approximately 20 per cent. Before accepting such negative results as evidence against the renal origin of hypertension, two questions must be asked: 1. In how many cases were the main renal arteries and their branches examined? 2. How many sections of the kidney were made? The same questions naturally apply to Bell's negative results in other types of cases. In a series of 107 cases associated with a large heart and known hypertension in which death was due to apoplexy or encephalomalacia, he reports negative findings in 14 per cent but positive in 86 per cent, in a subgroup of 42 cases in this series with a large heart but with no blood pressure recorded, renal arteriolar sclerosis was not found in 19 per cent but was present in 81 per cent.

In support of his view that hypertension and renal arteriolar disease are independent of each other, Bell cites his observations on 124 control cases in which the heart was normal in weight and in which there was no clinical hypertension. In this group he reports renal arteriolar sclerosis in 17.7 per cent, but as he says "It is to be noted, that the more severe degrees of arteriosclerosis are very rare in the controls—only 2 in 124 cases." Finally, with almost total constraint, he ends the paragraph thus: "It is clear that grade 1 arteriosclerosis may develop in older persons independently of hypertension, but the more severe degrees, grades 2 and 3 are very rare in the absence of hypertension." In other words, the type of renal arteriolar lesions found in hypertensives is, quoting Bell, "very rare in the presence of a normal blood pressure." Apparently impressed by his own data, Bell takes a guarded position on the relation of renal arteriolar disease to hypertension because in the summary of his paper just considered he writes "It is clear that severe renal arteriosclerosis may cause or intensify hypertension." Since there is no established quantitative relation between structural changes in the kidney and hypertension, may not less severe lesions also cause hypertension?

I have assayed the evidence in support of my thesis that a renal mechanism is the cause of arterial hypertension, not only in that observed in primary renal disease as every one admits, but also in that more common type hitherto called primary or essential hypertension. Disease, either inflammatory or vascular, affecting any organ except the kidneys does not produce a permanent

elevation in blood pressure in man. Furthermore, let us recall that experimental impairment of the blood supply to the kidney, and to no other organ in the body, results in protracted arterial hypertension. Finally, just as in the experimental animal, so in man, unilateral renal disease may be the cause of hypertension, and the removal of the diseased kidney may result in a return of the blood pressure to normal. In view of these facts, how can one eliminate the kidneys as the cause of hypertension?

In the light of both experimental and clinical observations, the correlation between arteriosclerosis, kidney disease and hypertension, which, as we have seen, has puzzled physicians since Bright, may now be stated as follows: Arteriosclerosis is the primary disease. This process when affecting the vascular system of the kidneys excites a humoral mechanism which produces a widespread vasoconstriction and thus causes hypertension. Whether this is the benign or malignant type depends on the progress and severity of the vascular lesions in the kidneys. Essential hypertension is a manifestation of renal vascular disease, and therefore it appears as one aspect of human arteriosclerosis, the nature of which is, as we all know, one of the greatest unsolved problems in medicine today.

OTOLARYNGOLOGIC PROBLEMS OCCURRING IN FLIERS

LEON D. CARSON, M.D.

Lieutenant Commander U. S. N.
WASHINGTON, D. C.

In this paper I cannot hope to present more than an outline of the application of this most important handmaiden of medical science to the physiologic problems imposed on the economy by the stresses and rapid changes of environment encountered in flying. This is particularly true in military flying in which the accomplishment of the task is considered of first importance and the stresses imposed on the pilot as of secondary significance. In airline or civilian flying every effort is made to avoid unusual stresses to passengers and to planes. In military flying, aircraft are designed to withstand the unusual physical stresses imposed by the necessity to outperform an enemy pilot who has a similarly designed plane and similar motives.

The flight surgeon's task, therefore, is first to select as pilots men capable of withstanding punishing physical and mental strains and, second, to maintain the physical fitness of this group of combatants at as high a level as possible and to surround them with every safeguard possible to protect them against the effects of an environment which was never considered in the design and specifications of the first model of *Homo sapiens*.

It follows, therefore, that aviation medicine is concerned primarily with those conditions which are essentially physiologic and subclinical. Malfunction and disease conditions such as would cause a patient to consult a physician are for the most part disqualifying for the occupation of military flying. When such complaints or disease develop in a flier and extensive treatment or surgical intervention is indicated, he is usually referred

Read before the New York Academy of Ophthalmology and Otolaryngology, March 18, 1942.

Revised and read before the Section on Laryngology, Otology and Rhinology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

to specialists in our naval hospitals and dispensaries for treatment

Quite a number of subclinical conditions which have been found to be incompatible with flying are frequently discovered in the routine physical examination for flying. Many of these are susceptible of correction and are referred to the otologist or the laryngologist for appropriate treatment. Some of these subclinical conditions are hypertrophied or diseased tonsils, adenoidal or polypoid obstructions, septal deviations and nasal abnormalities interfering with drainage or aeration of the paranasal sinuses. Diseases of the middle ear or a history of mastoid disease are considered disqualifying, and postoperative radical mastoid extenterations which have resulted in complete cure are invariably considered as disqualifying for flying. Chronic sinus disease, quiescent but destructive middle ear diseases, and so on, are in the same category.

On the other hand there are often presented relatively insignificant anatomic abnormalities or functional irregularities which have never aroused the interest either of the examiner or of his civilian medical consultant, which are definitely disqualifying in a candidate for aviation because of their known tendency to cause disability under the environmental conditions imposed in flying. When one considers some of the unnatural conditions imposed by flying, such as rapid changes of barometric pressure, extremes of temperature, air blast, propeller blade flutter or high noise levels, and their unfavorable effects on the normal ear or nasopharynx, the reasons for such meticulous discrimination become apparent.

In the following discussion I shall consider rather empirically the effects of flying on these structures, and for convenience I shall divide the subject into five subheads:

- 1 The nasal structures and accessory sinuses
- 2 The middle ear and eustachian tubes
- 3 The mouth and pharynx
- 4 The acoustic function
- 5 The vestibular mechanism

NASAL STRUCTURES AND ACCESSORY SINUSES

Adequate ventilation is of first importance with regard to the nasal structures and accessory sinuses. At altitudes exceeding 8,000 feet anoxia begins to develop and at higher altitudes may become severe. As the normal physiologic response to anoxia is an increase in depth and rate of pulmonary ventilation, any degree of nasal obstruction which interferes with free breathing is undesirable.

Obstructions due to septal deformity should be removed by surgical means prior to acceptance for aviation. Polypi are usually regarded as indications of ethmoidal disease and if found on routine examination are cause for rejection. Any unusual turgidity, dryness, "fish belly" pallor or other indication of allergy is cause for disqualification or for determining on a reexamination. Unfortunately many a young man anxious to get into aviation training has learned in advance of our causes for rejection. Occasionally polypoid degenerative changes are overlooked because the young man has received the collaboration of his own physician, who has judiciously applied a small nasal pack moistened by a vasoconstrictor drug just prior to the boy's visit to the examiner.

In the case of men who have deformed septums it is often the case that we hesitate to advise correction by the usual cartilage resection, because the septal deformity may be but part of the obstruction. Often there is such narrowing of the alar openings that an injudicious removal of septal cartilage may cause even further obstruction of the nostril unless the entire procedure is carried out as a complete nasal plastic operation.

Other things we look for are evidences of chronic sinus disease, for it has been the almost invariable history that flying aggravates the trouble and accelerates its progress toward disabling disease.

THE MIDDLE EAR AND EUSTACHIAN TUBES

Here is another and striking example of man's maladaptation to a new environment. Under ordinary conditions only slight changes in atmospheric pressure are experienced, and these changes are readily compensated for within aerated bony cavities in the skull, by connections to the outside atmosphere through nonpatulous ducts or tubes. These lie wholly or in part within bony structures and are lined with modified ciliated mucous membrane. The eustachian tube, leading to the nasopharynx from the middle ear, is a good illustration.

The inability under all conditions of barometric pressure variations encountered in ascents and descents in aircraft to maintain equal pressure on the two sides of the tympanum places stress on that structure, which frequently causes discomfort of almost any degree, ranging from mere annoyance to sharp and agonizing pain accompanying severe invagination of this sensitive membrane. Occasionally rupture and hemorrhage may occur.

In studying this syndrome one is impressed by the fact that release of pressure from the middle ear via the normal eustachian tube occurs with little if any discomfort and is usually symptomless regardless of the rate of climb or lowering of barometric pressure. Disturbing symptoms occur on descent or during the return to levels of increased barometric pressure. Partial vacuum within the middle ear causes engorgement of the capillaries lining the cavity, followed by extravasation and actual hemorrhage ("the aero-otitis media") described by Armstrong.

The anatomic structure and relationships of the eustachian tube explain this imperfect function. One may describe it as resembling an upper, larger, and a lower, smaller funnel with their stems in apposition. The upper funnel comprises about one third of the tube and the narrower lower funnel about two thirds. The walls of the upper are osseous with a closely adherent mucous membrane, having it patent at nearly all times. Any expanding gas finds ready exit through a patent tube. Low pressure chamber experiments have proved that even in sudden decreases of barometric pressure there is almost a complete absence of any ear symptoms, which suggests that the expanding gas in the middle ear immediately and easily finds escape through the tube.

In the case of the lower two thirds of the eustachian tube one finds a relatively unsupported collapsible structure with more redundant and turgescient mucous membrane surrounding, and within, its opening into the pharynx. Increase of pressure trying to find its way into the middle ear through this comparatively relaxed tube tends to close its opening more firmly, in which

respect it behaves like a flutter valve. So one finds partial pressure within the upper tube and middle ear tending to produce engorgement of the tubal lining, and positive pressures in the pharynx tending to close the comparatively soft or relaxed portion of the tube.

A vicious cycle is set up and it becomes necessary to employ artificial means of equalizing the pressures. This simply means in most cases bringing the tensor muscles into play by yawning or swallowing movements, closing the nares and blowing just hard enough to pass a bubble of air into the ear. In fact, merely closing the nose and swallowing usually suffices, the reason being that swallowing both exercises the tensor muscles and raises the pharyngeal pressure.

It has been repeatedly observed that in fairly rapid descents from high altitudes the first part of the dive causes no distress, whereas acute distress will begin at between 15,000 and 20,000 feet or at lower altitudes. The increasing density of the air probably has something to do with this. Air of higher altitude is about of the same density as helium or less dense. Rapid descents seem to be as well tolerated as slower descents by a good many persons.

Flight surgeons used to consider it their duty to warn pilots against unnecessary employment of the Valsalva maneuver, carefully explaining to them that any infection present near the ostium of the eustachian tube was likely to be carried into the ear. It was believed that "colds" and pharyngeal irritation were contraindications for the employment of this technique. But the truth of the matter is that in spite of almost universal autoinflation of the ears among our navy pilots, "head cold" or no "head cold" and disregarding sore throats the actual incidence of acute otitis media is found to be no higher among fliers than in the case of mere groundlings. Poppen¹ surmises that this is because gravity, ciliary activity and lymphatic drainage all join in returning minute amounts of infectious material introduced in this way into the larynx.

Occasionally flight surgeons see instances in which every possible maneuver fails to accomplish equalization of pressure—and these unfortunates are usually pitiable objects. When one of these pilots walks into my office, the diagnosis can be made from his facies and a casual glance at the clothing. The face registers acute misery, the eyes are reddened and lacrimose. He hasn't bothered to remove all his flight clothing before seeking relief. An inspection of the tympanum shows a pronounced retraction. If half an hour has elapsed since the accident the membrane has lost its luster and shows severe injection. Occasionally it appears actually hemorrhagic.

Treatment, of course, consists in rapid shrinking of the tissues of the pharynx in the region of the blocked ostia, followed by instruction to repeat the Valsalva maneuver. If this fails it is necessary to introduce air by means of the eustachian catheter. In such cases I prefer the introduction into the ear of hot iodine vapor.

Another important consideration is the character of the gas introduced into the ear by the autoinflation. If one happens to be breathing oxygen and inflates the middle ear with air having a rich percentage of that gas, unfortunate results may follow. A. R. Behnke has described cases in which high concentrations of oxygen have been introduced into the middle ear and

absorbed during sleep, producing more or less complete filling of the middle ear by exudate and hemorrhage. Mixtures of gases introduced into the middle ear must eventually come into equilibrium with oxygen percentages present in capillary blood, which are roughly 12 to 14 per cent.

A simple solution is always possible. If the air introduced is alveolar air it will approach the percentage composition of gases in solution in capillary blood and will very quickly come into equilibrium. Therefore holding the breath, exhaling, and inflating the ears at the end of expiration are recommended.

Closely related to this syndrome is the one occasionally seen following occlusion of the normally patent ducts communicating between the frontal and maxillary sinuses and the nasal passages. Much of the nasal and pharyngeal disorder preventing normal equalization of pressures between these spaces and the ambient air is believed to be due to the rather constant irritation of the mucosa by such things as air blast experienced in flying in open cockpit planes, chilling, and noxious and irritant fumes from engines. It is my impression that in older fliers one finds gross evidence of chronic inflammatory changes quite frequently.

Peculiarly enough, typical Bell's palsy generally believed to be caused by excessive exposure of one or the other side of the face to air blast, is of no more frequent occurrence in fliers than in nonflying personnel. In fact I can recall having seen but 1 case in an aviator in fifteen years.

MOUTH AND PHARYNX IN RELATION TO FLYING

Except in the cases of those few pilots who seem to become habitual mouth breathers as soon as they put on an oxygen mask, conditions encountered in flying seem to have little noticeable effect. Excessive dryness and irritation of oral and pharyngeal tissues is sometimes seen in these individuals. There is some doubt as to whether such irritation results from high percentages of oxygen or from use of a chilled gas. Pipe stem oxygen breathers used to show pronounced irritation of the mucosae of the mouth and throat after an hour or two. Now that oxygen is used from a mask one sees few signs of redness or dryness even in men who are mouth breathers.

Pressure changes due to rapid climbs often aid the dental office to diagnose a gas pocket in an abscessed tooth.

The usual run of nasopharyngeal ailments—chronic tonsillitis, Vincent's infection, chronic postethmoiditis and sphenoiditis with postnasal discharges—occur in flying personnel with no greater frequency than in nonfliers. Chronic sinusitis, if not amenable to treatment either limits or terminates a man's usefulness as a pilot.

THE ACOUSTIC FUNCTION

The impairment of hearing caused by changes of pressure in the middle ear is a purely transient phenomenon. Progressive otosclerosis seems to be neither benefited nor influenced in its inevitable course by flying. It is noteworthy in this connection that news stories such as those current a few years ago dealing with the miraculous return of hearing in the case of "old Mr. Glutz, who took his first airplane ride yesterday" are rarely seen today.

Higher noise levels which have resulted from more powerful engines, longer propellers and higher speeds

¹ Poppen, J. R. The Ear in Flying. *Laryngoscope* 51: 974 (Oct.) 1941.

do produce temporary auditory fatigue. Hearing is measurably impaired for considerable periods of time following prolonged flights, but this is considered as evidence of fatigue of the function and not due to pathologic changes. It is true that animal experimentation has demonstrated actual microscopic and even gross damage to the organ of Corti by noise levels exceeding the value of 130 decibels and frequencies of 4,000 cycles per second.

These represent levels of stimulation, however, which are very high, much higher in fact, than are encountered in aircraft. So we call it fatigue of the auditory function, a very convenient term with which to cloak our mere skeleton of information.

Fortunately, under the impetus of the all out national effort to survive, science is also going all out in an attempt to do its share, and well planned research projects have been set up under the direction of competent physiologists, psychologists and engineers so that the hope may now be entertained that some of the answers will shortly be made available.

The detailed answers are of importance to physicians, to the engineers who design aircraft and to the automotive world in general. Obviously it is highly impracticable to "dampen out" or to "sound proof" aircraft against noise and vibration over the entire range of the auditory spectrum. If science can give the answers as to whether sounds of low pitch but high intensity or high pitched sounds of great intensity are productive of the greatest fatigue, then by attacking the problem selectively it may be easily possible to minimize wear and tear on the tender subjectivity of man.

Air conduction of sound is probably not especially affected by change of atmospheric density, but the production of voice sound is¹. This represents one of the current problems in voice communication over aircraft radio. If one inhales quite deeply several times a gas of 20 per cent oxygen and 80 per cent helium and then attempts phonation, the resulting sounds which issue forth are startling. One's incredulous ears pick up an emasculated or plaintive bleat which sounds like a Mickey Mouse animated cartoon. The reason, of course, is that the pitch and intensity of the spoken syllable are changed and weakened by a gas of decreased density. So it is with any respiratory gas mixture at high altitude. Laryngeal and chest resonance are greatly reduced. The vocal cords in adapting to the less dense gas change their amplitude. Special microphones are being devised to pick up and transmit these weaker voice sounds. Present microphones just won't do the job properly.

Recent investigations as to effect of noise on hearing seem to indicate that higher frequencies of noise intensity of greater than 100-110 decibels will cause temporary deafness but that recovery is usually complete within eight to forty-eight hours, as determined by audiometry.

Time is a factor in such injury, for example 110 decibels for twenty seconds may cause no demonstrable change to the organ of Corti in experimental animals, 120 decibels for twenty seconds may cause microscopic evidence of damage, 120 decibels for thirty to forty seconds causes much more evident damage.

Pilots who show evidence of hearing loss after years of flying usually show this loss principally in the range of audiometric frequencies 1,024 to 4,096 or higher.

Whether hearing loss is measurably greater in fliers than in persons engaged in other occupations in which there is long exposure to noises of high level is hard to tell.

Now that cockpits in aircraft are provided cowling and much flying in larger enclosed aircraft is being done, I am convinced that damage to hearing should be less than it was a few years ago.

To me, headset, noises and static are much more disturbing in aircraft than any other noises. Head phone static frequently reaches the level of sharply painful stimulation. I am convinced that loss of hearing acuity for higher frequencies is principally due to this one factor. Unfortunately much experiment and research remain to be done before any expressions of opinion can be accepted as reliable.

THE VESTIBULAR MECHANISM

There are two forces in nature to which all animal and plant life are phylogenetically conditioned. One is never conscious of either of them in a normal environment, or when employing a normal method of locomotion. These forces are those of gravity and of pressure. Often the two act to maintain a body in equilibrium with its environment, as in the case of the fish with its swim bladder.

Walking or running, in man, is a series of falling and arresting movement. Here equilibration is said to be kinetic. When one is lying prone or supine, gravity is balanced by a resisting force which exactly counteracts it. This is termed static equilibrium. In resting or in progressing over the earth's surface, man maintains either static or kinetic equilibrium through the unconscious employment of a number of sensory stimuli by which he is made "aware" of his attitude relative to gravitational direction.

The several receptors which give us this awareness are tactile (exteroceptive) stimuli, labyrinthine, visceral deep muscle or pressure (proprioceptive) stimuli and stimuli mediated by the special senses of seeing and hearing, the so-called teleoreceptors. Poppen² has said "It so happens that in flying we can have ultimate recourse to only one," meaning, of course, vision.

In learning to fly, one has to learn to ignore most of those stimuli on which, as a terrestrial being, one has placed chief reliance and to substitute therefor a completely visual adaptation. Some of these sensations, particularly the labyrinthine, merely serve to confuse the flier. In the early days of aviation much effort was expended by the physiologist and the otologist and many profound and elaborate theses were written in an attempt to explain the importance of this function to the business of aerial equilibration. Many famous differences of opinion arose as to which function ranked first in importance, visual, vestibular or proprioceptive. The otologist favored the labyrinth, the ophthalmologist naturally ascribed greatest importance to the visual organ, and the old time aviator tolerated both views but insisted on "flying by the seat of his pants," and a railroad track was his most valued navigational instrument.

Times have changed. We still describe the function of the labyrinth, but only to excuse its misbehavior. "Seat of the pants" stimuli, when a plane is in normal flight and in stable aerodynamic relationship to all forces acting on it, are of precisely the same value as when the seat is in firm contact with an automobile.

² Poppen, John R. George Washington University and School of Aviation Medicine 1940

cushion. But when the plane executes maneuvers in which these aerodynamic forces become of much greater magnitude or amplitude corresponding degrees of labyrinthine stimulation occur, which are not only misleading but deeply disturbing. These overpowering stimuli result from such maneuvers as snap rolls, power spirals, spins and prolonged tight turns.

The degree of labyrinthine stimulation under such circumstances produces concomitant nystagmus and vertigo and affects the higher cerebral centers. One becomes acutely conscious of the stimulus and acutely misinformed as to orientation.

Illusions as to their position within the plane as well as orientation of the plane in relation to the earth's surface are familiar to most pilots who have done much flying, and they occasionally refer to a phenomenon known to the fraternity as "the leans." Take a specific case in which a plane "on instrument" flight in fairly smooth air has undergone a gradual depression of the right wing. The pilot from his instruments is made aware of this and by applying the left aileron brings the wing up level on the artificial horizon.

The sinking of the wing was gradual and was not sensed by vestibular function. The bringing up of the wing was more rapid and caused vestibular stimulation, and as a result of this leveling the pilot feels as though he were now actually leaning to his left, and he responds by leaning to the right or to what his subconscious awareness tells him is an upright position.

If experienced, the pilot, by referring to his instrument, becomes aware of the false attitude and is able to force his illusion from his consciousness. If inexperienced or if he does not refer to his instruments repeated depressions of a wing out of trim and recoveries will often find the pilot leaning far away from the vertical after several corrections. This does not happen if the weather is clear and the pilot is able to fly "contact."

I subscribe to the idea that the visual function is the most important. Certainly it dominates the others. For example, following recovery from a fast right spin the pilot, if flying blind, will receive from his overstimulated labyrinth the very real illusion that he is now spinning to the left. He makes necessary correction and again reverts to a right spin.

If there is any degree of horizon visible, an exactly opposite phenomenon often occurs following such a spin. After rotation to the right—aid arrest of rotation—

- 1 Endolymph flow or pressure is to the right
- 2 The slow component of ocular nystagmus is to the right
- 3 The visual illusion is that the horizon is still sweeping to the left and that the plane is turning to the right
- 4 Corrective procedure is to follow the horizon, and a left spin often results

All this in spite of the fact that the vestibular illusion is that of turning to the left. The eye says "no," we're still turning "right," and the conscious mind accepts the visual information and suppresses the labyrinthine.

Vertigo is the disturbance resulting from disharmony between the organs of equilibrium. The two most highly specialized being the labyrinth and the oculomotor apparatus, it is easy to believe that conflicting impressions received by the subconscious from these two can cause the severest symptoms. The visual function being most important in flying, has led to the development of the paradox use of the eyes alone and to the exclusion of all other senses whenever one must "fly blind."

ABSTRACT OF DISCUSSION

DR. R. J. HUNTER, Philadelphia. The commander described the sensations which come to an aviator in a tailspin or in the beginning of a tailspin. He told how, when the wing is low, and one suddenly comes up and stops, the person, of course, has a sensation of movement in the opposite direction, if the eyes are closed, and, if the eyes are open, he will have the illusion in the other direction. Those are all things we are well acquainted with in the question of equilibration, and they are functions which are inherent in the human mechanism. The commander said in his paper that he felt that those sensations should be suppressed. These functions of the labyrinth come from our primitive ancestry long before we had ears and eyes and they are so basic that they are an integral part of the work of our eyes and our ears. I agree with Commander Carson that the eyes are the dominant factor in equilibration. In other words as one moves or as objects move about one the impressions come in through the sight, are passed on through the eyes, through the muscles of the eyes, to the internal ear, and we react accordingly. One unfortunate thing with all this business of equilibrium is that the literature is complicated. If one starts to tell about the pathways and to tell about von Bechterew's nucleus, and so on, the students and the listeners are soon fatigued. They refuse to listen. But, as a matter of fact, the actual reactions are so simple that any one can understand. They are so simple that every acrobat who learns to do something has, of his own volition, learned how to perform those functions. Every time we cease moving in a given direction, muscles are automatically put into play to pull us in the opposite direction. The commander's mention of the aviator about to take his tailspin reminded me of when I went to Park Field in May 1918 as a flight surgeon in the army. There were mottoes all around the border of the mess hall, one of which was "Beware of the deadly tailspin." Now, about that time a French aviator had discovered that by putting his head down in a certain position and holding his stick and his rudder in the right way he could come out of a tailspin and prevent himself from going into another. In other words, that man empirically discovered what to do to overcome these unfortunate sensations that the commander calls attention to. That is a clue to a great deal that could be done at present to minimize the sensations. We have heard from the psychologists about suppressing our desires, and now the commander wants us to suppress something in addition. He wants us to suppress these sensations that we get from the equilibrium apparatus. Instead of suppressing them, let us try to understand them and act accordingly.

DR. A. H. ANDREWS, JR., Chicago. Hermann in Austria has described a condition which he calls submucosal hemorrhage of the paranasal sinuses, which is the result of very rapid descent during the dive flying. He has described the roentgenologic aspects of this particular condition and the treatment. I should like also to mention the work of Roth, Ivy and myself with regard to the use of altitude in the treatment of paranasal sinus disease. We have treated over 100 patients, taking these patients up to an altitude generally of 8000 feet in a decompression chamber. In this group only 4 have had the complication of aero-otitis media, and every one of these patients had an acute cold when he was taken up, and the trip was definitely contraindicated. In the presence of sinus disease and altitude we did not have the aero-otitis media in as large a percentage of cases as one would expect. We encountered eustachian obstruction not infrequently, and we handled those cases in this way. On the way down if the men experienced eustachian symptoms which were not relieved by swallowing or drinking water or chewing gum, they were taken back up slowly until the eustachian symptoms disappeared and then taken down, as soon as the symptoms recurred, up again, working gradually, taking plenty of time, rarely taking more than half an hour. The question comes up: Is this applicable to our fliers by the use of a decompression chamber after they have come down, taking them back up and bringing them down more slowly, and in steps? A third point concerns research that a group with which I am associated has been doing on the recording of the movements of the ear drum under the Valsalva

maneuver, and under controlled pressures applied to the ear drum through the nose and mouth. It has been possible to get a very nice tracing of the movement of the ear drum. In working this out, I used myself as a subject and to my surprise found that my right drum had much less excursion than my left drum. In childhood I had chronic otitis media for a number of years and have a little impairment of hearing in that ear. It was demonstrated that by this method of examination there was definite impairment of motion in the middle ear. Of course, the thing we were interested in was not that but, rather, working out quantitative methods of expressing eustachian obstruction. That brings up a point which I feel is very encouraging, and that is merely that I believe that our clinical otology is going to see rapid advancements as a result of the research and study that is being done on the eustachian tube in connection with our war effort.

DR HERMAN J. STERNSTEIN, Boston. I was interested in Dr. Carson's observations concerned with the effect of nasal obstruction on the patency of the eustachian tube. In experiments being conducted at the Massachusetts Eye and Ear Infirmary I have attempted to correlate the effect of nasal resistance on tubal patency and sound transmission. Nasal resistance determinations were made by the method previously described. Patients with normal and obstructed noses were studied with a new type of rebreathing apparatus designed to permit a maximum range of pressure up to 25 cm. of water regulated on a time factor basis. By means of an airtight rubber tube connection for sipping water it was possible to measure accurately the equalizing efficiency of the eustachian tubes within the determined range of pressure at each swallow. It was found that in the obstructed nose the equalizing efficiency was definitely impaired and decreased. After the administration of amphetamine or neosynephrin it was found that the tubal patency and equalizing efficiency was improved by 50 to 75 per cent. The effect of tubal pressure changes on sound transmission was elicited by the Weber test. Sound lateralized readily to the more patent tube. In tubal obstruction lateralization and failure to equalize sound was quickly indicated by the patient and the result measured on the manometer.

DR LEON D. CARSON, Washington, D. C. I am sorry I did not have the opportunity to finish the paper, having slightly miscalculated the reading time. Dr. Hunter's remarks were very pertinent. I do not believe there is any disagreement between Dr. Hunter and myself as to suppressing stimuli from the middle ear. In my paper I developed the thesis that what we are teaching our aviators to do in cases of conflicting stimuli existing between visual function and the middle ear is to disregard any impressions as to their position relative to space or to the plane and to depend solely on the visual function. This is rather easy to do, as one almost involuntarily depends, first of all, on the visual function in orientation in space. Dr. Andrews brought out several points. I have gone over the work which is under his direction and have seen several reports of treatment of middle ear disease with variations of barometric pressure, induced by changing pressures equivalent to about 2,000 feet altitude, sort of a churning back and forth, using a low pressure chamber. Of course, without attempting to go too deeply into how much actual aeration is accomplished by this means, I should like to bring out that we are dealing with military plunges from somewhere around 30,000 feet to as low an altitude as necessary without any regard for equalization of pressures. One other point brought out, namely, research dealing with the excursion of the tympanic membrane. We have learned in our own low pressure chamber experiments some interesting things. If our subjects to the chamber, who commonly experience difficulty with equalization of pressures in the middle ear, are distracted by some other momentous event—in other words, if they become a bit anoxic or suddenly worried about their physical condition and forget about this problem, they frequently have no trouble. Another thing discovered recently is that in chambers where we have sound equipment and we play a piece of popular music during the descent, so that it is being recorded and transmitted to the individual earphones, most subjects have no trouble. It may be that this function, like respiration, is one that carries on best only when we do not pay too much attention to it.

HEALTH PROBLEMS IN WAR HOUSING

DONALD K. FREEDMAN, M.D.

Passed Assistant Surgeon (R) United States Public Health Service
Medical Adviser to Federal Public Housing Authority

WASHINGTON, D. C.

There is little precedent in this country for action with regard to the health problems arising in connection with wartime public housing. The United States entered the first world conflict late in the course of the war. War industries generally made use of existing plants, enlarging them or stepping up production. Local communities were generally able to house the new workers fairly readily.

In this war, production is on a greater scale. We are supplying other nations with huge amounts of equipment. We have had little time for preparation. As a result of the rapidity with which production has had to be organized, severe dislocations in population have occurred. Almost overnight communities have arisen in the midst of barren regions, and towns have become cities without warning.

PUBLIC HOUSING

These rapid changes have created extraordinary housing problems. As a result of the unbearable and dangerous living conditions in some regions, many workers left their jobs and moved to other defense areas. Industrial production was hampered seriously by such constant shifting of workers. Public war housing undertook to solve this problem in the quickest way possible.

But large new housing projects, some of them in areas previously but sparsely settled, also present many problems related to health and sanitation. Such problems are water supply, sewage and garbage disposal, environmental sanitation including mosquito control, hospital, medical, dental and nursing care, recreation, safety and health education. The situation with regard to these needs in war housing projects is not one in which we can afford to adopt a *laissez-faire* attitude. It concerns every one of us in a most vital way. Approximately 435,000 dwelling units are occupied, under construction or in the planning stage. This represents at 3.5 persons per family more than 1½ million tenants, of whom well over ½ million are, or will be, actively engaged in work which means the difference between victory or defeat for this nation and its allies.

For this reason, public housing authorities have naturally been interested in determining the availability of the health and sanitation facilities necessary to protect their tenants, and in making such facilities available when they are lacking or inadequate.

Federal housing projects constitute a true part of the communities in which they are located. Their only immunity is from taxation, being otherwise subject to civil and criminal law except where located on military reservations. However, payments approximate to normal taxes are made to local communities in lieu of taxes. Public services such as police, fire and health protection are available to the tenants as well as to other citizens in the community, although in many instances such services are so inadequate that they may be considered unavailable.

SANITATION

When heterogeneous groups of people with varying degrees of immunity against communicable disease are thrown together, with unknown "carriers" of disease in their midst, they are particularly susceptible to epidemics. Careful attention must therefore be given to basic sanitation. It has been necessary to install protected plumbing. To this end experts have been called on to establish new plumbing codes. Individual modern plumbing has become a reality to thousands of families for the first time.

Many such persons are also enjoying a safe water supply for the first time. This should result in a decrease in the incidence of water borne diseases. Those accustomed to contaminated wells and other impure sources are now getting their water from city mains, which, with the aid of federal funds, have been enlarged in order to take care of the increased demand.

New military and industrial communities have also been threatened with overloaded sewage disposal systems. Outmoded or inadequate treatment plants have been, and are being, enlarged or replaced in many places to handle excess loads created by population growth. Studies of stream pollution have had to be made in order safely to expand existing disposal systems. Engineers from the district offices of the U. S. Public Health Service have been called on by local and state health departments to assist in this work. Where a local sewerage system is operating at capacity and funds have not been available for enlargement, public housing has constructed its own sewerage.

All such health and sanitation operations should be undertaken in close cooperation with local health authorities. In this way, maximum effectiveness is obtained. When local health agencies have not been consulted by the housing authorities, difficulties have arisen. In a large Eastern city, a housing site was chosen in swampy land. The area was filled in and construction was completed by the local housing authorities before it was discovered that the cellars were flooded. Even then the housing people did not go to the health department for assistance. Such a situation could have been prevented simply by drainage of the swamp area in the beginning. In another instance, water mains and sewer lines were laid in the same ditch. Through a close working relationship between housing and health, however, many departments have developed housing as a specialty within the field of public health itself. When housing and health activities are harmoniously combined in this fashion, with the aid of federal consultation and funds there is a minimum opportunity for the errors which defeat the very purpose of public housing.

When for strategic or other reasons, air fields or ordnance plants are constructed many miles from a town or city, it is probable that there may be no health department whatever. At best, if a health department does exist, its facilities are insufficient to handle a population that is often doubled or tripled. This is especially true where the health officer is serving part time in his official capacity and is also in private practice.

Public housing in wartime is necessarily located as close to an army or navy reservation, air field or war plant as is possible under local conditions. The project may be constructed on an army post or adjacent to one, as many as 5, 10 or more miles from the nearest town. It cannot be expected that a fully organized, perfectly

functioning health department will be available in each of the hundreds of areas now engaged in essential production. On the other hand, it is to be expected that, as soon as an area serves war needs, the local health department will anticipate or attempt to meet all public health problems. Any loss of man-days of work due to ill health means a proportionate increase in the duration of the war. Already, nonindustrial illness accounts for 90 per cent of the 400,000,000 man-days lost annually from work in industry. A large part of this illness is preventable or reducible.

PUBLIC HEALTH SERVICES

In order to face this situation realistically, it has been necessary to establish public health services where none existed before or to bolster health departments whose personnel has been depleted by the calling up of reserve officers. Unfortunately, the distribution of these additional facilities has not always been effected so as to benefit those new or outlying sections of town where the need is greatest. A large percentage of the war workers are situated in new residential areas where clinic and other health services do not exist. Although these workers may utilize services available elsewhere in the community, too many obstacles chief of which is distance, stand in the way. Transportation facilities are often poor. With the advent of the rubber and gasoline shortage, this situation has become worse.

War workers congregate from many parts of the country. Many of them have not previously been exposed to health department activity. These people are not acquainted with the preventive services ordinarily provided or with their importance. But if all tenants and their families were aware of the importance of protecting their health in every way possible it is doubtful whether a very large percentage of those needing service would seek it in view of existing obstacles.

In view of these circumstances, space has sometimes been created or adapted for clinic use within the housing projects themselves. This is done in one of three ways. 1. A dwelling unit may be converted into a health center. 2. A building may be constructed for the purpose. 3. Space may be set aside in the administration building. In any case the service is operated by the local or state health department. Tenants are attending these clinics in increasing numbers.

As an example, there is a housing development with 350 persons in a Southern city. It is located somewhat outside the main section of the city. No clinic or public health service facilities were available which did not involve a tedious bus and trolley ride into the center of the city. Several cases of communicable disease occurred in the area surrounding the housing project. The children both inside and outside the project play together. With the excellent cooperation of the local board of health, a clinic was established in two adjoining dwelling units. It now serves all persons in the entire area. A complete program is providing clinics for vaccinations and immunizations, preschool physical examinations, tuberculosis, venereal disease, crippled children and antepartum work. There are classes and demonstrations for adult education. Some of the families have been vaccinated for the first time. Well baby conferences have not only improved the health of the children but, unfortunately for the busy physicians, increased their work as a result of referrals.

The foregoing are briefly stated, the problems connected with the preventive aspects of war housing health

and sanitation. The most important consideration in evaluating this work is that it concerns essential service to concentrated groups of war workers, every one of whom has been certified as eligible for a project dwelling by a military post commander or by the personnel director of a war plant. By serving such housing areas we are reaching, without waste motion, these key people as well as many in the immediate vicinity of the project.

Now let us consider the subjects of hospital and medical care.

HOSPITAL CARE

The hospital problem is very serious. Although public housing tenants are not the only ones affected, lack of hospital facilities is a matter of serious concern to them. Eighty per cent of bed capacity is considered the maximum at which a hospital can operate efficiently, yet many institutions continually have occupancy rates of 100 per cent and more. Patients are cared for in hallways and, in some places, in cellars. There is simply no choice in the matter. When a hospital is crowded and patients are brought in in an emergency, they must be put somewhere. Often they must be held in emergency rooms for several hours.

An even worse situation exists with regard to delivery rooms. Almost all industrial and military communities have a high birth rate. Regulations for the protection of delivery rooms are violated frequently, also without choice. Patients are sent home after three days of postpartum care to make room for others. Many operating rooms are in use practically twenty-four hours each day, with scarcely enough time for proper cleaning. Increased numbers of highway accidents have added to the troubles of the hospitals, as has the diminution of staffs.

More than seven hundred requests for government aid in the construction of new hospitals, additions to existing hospitals or health centers have been received from approximately five hundred communities. Each request has been studied by the U. S. Public Health Service and more than three hundred of the proposed projects have been recommended as justified by wartime conditions and needs.

MEDICAL AND DENTAL CARE

A problem of equal magnitude is the provision of medical and dental care for occupants of war housing projects. Under ordinary circumstances such needs would readily be met by local doctors, but wartime conditions change the picture completely.

At the beginning of the defense program, some towns were able to absorb considerable numbers of defense workers without too much shock. The degree to which the impact was felt depended largely on the size of the town. For example, a city of 30,000 or 40,000 could handle several thousand additional workers, the same number entering a town of 500 created unbearable situations. In some of the areas there were enough physicians and dentists to satisfy normal demands, in others a shortage already existed, if judged by any adequate standard. But, regardless of what the situation had been, with the influx of newcomers it was not long before the ratio of professional men to population was severely upset.

In large cities the effect of an increased population is not so noticeable. There the relative excess of doctors may take care of expanding needs for some time. A noteworthy exception is the Washington, D. C.,

metropolitan area, where the population has increased from approximately 965,000 to over 1,150,000. With the entry of many local physicians into the armed forces, it is now often difficult for newcomers to Washington to secure medical services. A patient may phone as many as five or six practitioners before he succeeds in getting one. Naturally, the physician gives preference to his regular patients, and he may be so busy that he is unable to make a home call to a new patient until the day after the request has been received. Offices are so crowded that waiting for several hours is commonplace. Likewise, dental care can be secured by many persons only after two or three weeks of waiting. By working long hours at a strenuous pace, physicians are striving to serve all the people who require their attention and at the same time maintain a high quality of service.

Small cities and towns, on the other hand, generally present a more extreme picture. For example, the population in a town in the South has grown 900 per cent—from 500 to 5,000. There were, and still are, two physicians but no dentists. One of the doctors spends half of his time as mayor. Thus there is a ratio of three tenths of a doctor per thousand of population. The nearest hospital is 27 miles away, and it is overcrowded. As a result, many deliveries are performed at home. Home deliveries were by no means unusual in this region before the boom, but for many of the people living in that town today home is nothing but a temporary shack or a trailer.

Consider a larger city in the Far West. The population was 15,000 in 1940. At present it is over 30,000, and it is still growing. The doctors there now serve 65,000 persons, including those outside the city limits. The number of physicians has decreased from about thirty to twenty. Again, this is a ratio of less than one third of a physician to 1,000 inhabitants. Here public health nurses provide the only medical care for cases of communicable disease because physicians do not have the time. Doctors are working day and night with very little rest. The quality of care is dropping because a physician cannot treat 40 or 50 patients a day and do them all justice. Specialists' services have become unavailable because the practitioners have entered military service. This would be serious enough in peacetime, but in wartime it is a matter of grave importance to the nation as a whole because this community is playing a vital part in maintaining our navy at fighting strength.

These situations are cited only to show how they might properly be remedied. Where health departments have been understaffed, the U. S. Public Health Service has lent professional personnel, selected and trained especially for emergency duty in such areas. At the present time, approximately one hundred and fifty physicians are assigned to such duty with state or local health agencies in critical areas throughout the country. Including public health nurses, sanitary engineers and other specialists, almost seven hundred professional health workers are now being utilized for services of this type. Many of them have been assigned to federal housing areas or to activities which serve the tenants therein.

In every area where more physicians and dentists are sorely needed, their number is decreasing instead of increasing. Individual physicians and dentists as well as medical and dental societies have asked, and are asking, for help. They are urging that more practitioners be sent to their communities to relieve them.

of some of the overwhelming burden under which they are now struggling. This is a reversal of the usual situation, in which additional competition is apt to be discouraged. Actually, some men are ready to enlist in the armed services simply to escape the unbearable strain of practice under present conditions.

One solution, as far as housing project areas are concerned, is to have one or more practitioners serve primarily the housing projects. Such a method would take care, at least in part, of a large group consisting almost entirely of new families. It would save the time and energy of many doctors who would normally be summoned individually for home calls. It would also mean important economy of tires and gasoline for both doctors and patients. Another remedial measure would be to have professional men who are ineligible for military service, and women practitioners, relocated in towns where they are badly needed.

Housing authorities must also be concerned with the number and types of available specialists. A few thousand tenants are unable to support specialists, but it is to their interest to have specialists readily accessible. Again, this serves to emphasize the point that housing developments are not usually self contained, independent units but rather an integral part of the entire community.

What has been said about medicine also applies to dentistry, but to a greater degree. The ratios of dentists to population last year were in general about half as high as those of physicians. This year they are, of course, even lower. Dentists are needed to supply care for public housing tenants as well as for the communities in which the projects are situated.

CONCLUSION

If the health of war workers is to be maintained, it must be done by a concerted attack on all aspects of the problem. This includes the provision of adequate public health services, sanitation facilities, medical and dental and nursing care, industrial hygiene and accident prevention services, and mental hygiene programs. Public housing is simply a cog in the whole wheel of production, but the tenants constitute the wheel itself. In a large measure, the war will be won or lost by these tenants.

ABSTRACT OF DISCUSSION

DR JOSEPH W MOUNTAIN, Washington, D C. Dr Freedman has accurately described the situation but, I fear, he has understated its implications. There has been a vast shifting of our population without any corresponding adjustment of community services. The sudden influx of people into the new cantonment and war industry areas has actually overwhelmed such meager sanitary conveniences and professional resources as these communities normally possess. Through the Community Facilities Act the federal government has endeavored to assist the affected towns in expanding water supplies, sewerage systems and hospital accommodations, however, the shortage of critical material and manpower is seriously interfering with the program, and I fear it may ultimately defeat the purposes of the act. Nearly a year ago the Public Health Service called attention to a developing situation in respect to shortages of professional personnel and offered to be the medium through which physicians and dentists desiring relocation might get information concerning the communities needing their services. Numerous inquiries have been made by prospective candidates for such openings, but to date we can take credit for the placement of only five physicians and two dentists. The reasons why this scheme has not been more productive of results may be summarized in two statements. Young physicians, because of uncertainty in relation to Selective Service, do not care to make the financial outlay incident to opening an office. The older

physicians are now busy in their present locations and do not care to accept the inconveniences and the hazards of boom town practice. We have evidence that the present difficulty in securing medical care is the cause of much industrial absenteeism. As the manpower shortage becomes more acute, neglected illness may seriously interfere with the successful prosecution of the war. I am convinced that the undirected forces of supply and demand will not insure the most effective utilization of the depleted professional resources during the present national crisis. I further believe the need of medical care for workers in war industries and especially for those in boom towns, is so great that it should receive appropriate consideration in the future from the Procurement and Assignment Service and other agencies concerned with the provision of medical and dental services.

DR A S LEVEN, Chicago. In this all out war production, machines alone cannot win a war. It requires human beings to operate machines. These individuals must be healthy people to produce efficiently. It has been estimated that workers losing one month's time from work would build two heavy cruisers, four hundred and forty-eight medium tanks or thirty-two thousand light tanks. It has been stated that nonoccupational diseases far outrun those arising out of or in the course of employment causing many man hours loss in production. There is a leak in our productive capacity, and this points definitely to a lack of adequate medical care of our industrial and civilian medical needs for war production efforts—a luxury which we can ill afford at this time. Our armed forces receive the very best attention possible whether the illness is due to influenza, venereal infection or a bullet wound. Our army of workers, and a far too great a number of our population who are indispensable in this production scheme, have no such facilities. Our home front must be considered in the same manner as our armed forces on the battle front. Unemployment is a source of waste to our national economy. Its concomitants, malnutrition, unnecessary ill health, bad housing, are a waste to our national health. The waste of human ability and skill which our educational, economic and social systems have tolerated and permitted in the past must no longer be tolerated. It can, it must, it will be eradicated.

DR H R O'BRIEN, Hartford, Conn. To what extent are these new housing projects being supplied with clinic quarters, rooms? I have seen one that has been and several that have not. If the doctors are going to work in the community or near the community, they need clinic quarters.

DR GRADIE R ROWNTREE, Louisville, Ky. Should people in housing projects be furnished medical care by municipalities free?

DR DONALD K FREEDMAN, Washington, D C. In regard to the provision of favorable health facilities, there might be two types that we talk about, preventive and therapeutic. We are thinking of the entire picture, which concerns both measures. Specifically the federal Public Housing Authority which now embraces all the public housing agencies formerly distributed among some fifteen governmental agencies, is attempting to encourage the provision of both types of facilities by cooperating with physicians and dentists and with public health departments to make available whatever space is necessary. In other words, a physician who desired to relocate in a housing project where, in a defense area there was an inadequacy of medical care would be able to work out an arrangement with the public housing people to have an office there and possibly living accommodations. Now, housing areas of the type that we mention may have anywhere from a hundred people up to twenty thousand people in a single new housing community, and almost all, especially the larger ones, have a serious need for additional physicians. A new community of fifteen or twenty thousand which is built outside a city or town or in the wilderness does not have much medical care, usually no physicians, no government doctors or any other, unless a doctor comes into it on a voluntary basis and desires to establish practice. The same type of situation exists with clinical facilities for a public health department. If the local health department is interested in supplying the public health needs that Dr Emerson speaks about, for these workers and their families and others, they may make use of space in the housing project

to conduct the types of clinics necessary. In regard to the free medical care given by municipalities, it certainly is not the intention or the desire of the federal Public Housing Authority to give such care to occupants of defense or war housing. The tenants of housing projects are considered in exactly the same relationship as any other persons to the community as a whole. They are part of the community. The tenant should pay for medical care in the same way that others do, however, it is true that many of the tenants in housing projects earn as low as \$800 and \$1,200 a year. They may have families, up to three or four or more children, so that some percentage of them is in the category in which we find the very lowest income groups.

AMPUTATIONS IN WAR

NORMAN T. KIRK, MD

Colonel Medical Corps U. S. Army

BATTLE CREEK, MICH.

Experiences in World War I demanded an order that no wound should be closed by primary suture. Even with the advent of the sulfonamide derivatives it is not believed that primary suture is safe in extremity surgery under war conditions. This was further proved by reports of infection which followed debridement, the application of sulfanilamide and primary closure of wounds at Pearl Harbor and by reports in the *Lancet* from experiences on the Libyan front. All wounds closed by primary suture or tightly packed were found grossly infected when the patients arrived at the base in Egypt.

Methods of amputation might be classified as follows:

- 1 The guillotine or open method: circular or flapless type, flap type.
- 2 The closed type of amputation (amputations at site of election where flaps are fashioned and closed by primary suture).
- 3 Repair of the guillotine stump: (a) Plastic closure, (b) Plastic resection, (c) Reamputation.

Fig. 1—Skin traction for which four longitudinal adhesive strips are used with two applied circularly to prevent retraction of the soft tissue following the circular flapless guillotine amputation. The hexagonal spreader has four buckles to which to attach the adhesive traction rope pulley on the bed end and the weight to effect traction. (Amputations. Lewis's Practice of Surgery.)

The word "guillotine" is a misnomer; the circular guillotine amputation is not a "chop" amputation, as the word implies. In the classic operation the skin of

the extremity is cut through circularly around the extremity and allowed to retract; the fascia is likewise cut through at the level of the retracted skin; the muscles are cut circularly, the outer layers first and, as they contract, deeper layers, until the bone is reached. The periosteum is cut through circularly with a knife, at which point the bone is sawed through and the extremity removed. No periosteum or endosteum

Fig. 2—Appearance of wound after completion of guillotine flapless amputation through a compound fracture with chronic osteomyelitis and sequestration with destruction of the knee joint and an unhealed amputation through the leg.

is removed, as this leads to infection of the bone and sequestration. Care is taken not to strip the attached periosteum from the bone by muscle retraction, as spur formation may occur.

Large vessels are doubly ligated by no. 2 plain catgut, silk or cotton thread. Muscle bleeders are best transfixed by suture, fine material being used. Large nerves are pulled down, ligated, injected above the ligature with 95 per cent alcohol, cut with a knife and allowed to retract with the intramuscular septum. Small nerves are pulled down, crushed with forceps, cut and similarly allowed to retract. On completion of the amputation the stump is concave, the sawed end of the bone being shorter than the skin, fascia and muscle layers of the extremity.

An oblique rather than a true circular method may at times be employed to advantage.

In the flap type guillotine, flaps of skin, fascia and muscle are fashioned and are either pulled together over the stump end by adhesive, if the wound is not badly contaminated, or are packed open if badly infected.

If early secondary closure appears possible and the patient will not have to be transported elsewhere, this method may be indicated. The method is objectionable in that it requires more shortening of the bone than the circular type, but this may not constitute an objection if there is an excess of normal soft tissue. Flaps interfere with proper drainage if infection is present or develops; the area of exposed tissue is greater; the flaps frequently slough and become deformed during healing, and the main objection is that flaps interfere with proper and essential skin traction after amputation.

POSTOPERATIVE CARE

Immediately following the circular or flapless guillotine¹ (fig. 1), four strips of 2½ inch adhesive are applied, equally spaced, to the skin of the stump, extending to the margin of the wound and secured by two

or more encircling strips. The adhesive beyond the stump end is folded back on itself. The four ends are secured to a hexagonal wooden spreader by four buckles that are secured to the spreader by webbing and tacks. A cord from a hole in the middle of the spreader runs over a pulley on the foot of the bed to which is attached

Fig. 3—Ace Adherent (skin glue) stockinet and bandage used to effect skin traction as a substitute for zinc oxide adhesive. The dressing of the stump is held in place by the stockinet. This shows application of skin traction using stockinet and Ace Adherent.

a bag in which 6 to 8 pounds of weight is placed to produce traction.

A piece of stockinet of proper size may be secured to the skin of the stump with "Ace Adherent" (skin glue) (fig 3), in lieu of the adhesive plaster. The traction must be continued until the wound heals, which in a thigh will require some six weeks (figs 4, 5 and 6). The gauze that has protected the stump end while the skin traction was being applied is removed, from 5 to 10 Gm of sulfanilamide or a mixture of this drug and sulfathiazole is rubbed well into the stump end and the wound is covered with petrolatum or bismuth iodoform paraffin paste gauze. The wound is dressed and bandaged and is redressed infrequently unless severe infection occurs. It should then be treated with diluted

Fig. 4—Appearance of guillotine flapless amputation of thigh six days after operation necessitated by infected knee joint. The stump is being treated with diluted solution of sodium hypochlorite.

solution of sodium hypochlorite, or a daily pack of azochloramid may be used until all sloughing of tissue disappears (fig 7).

If skin traction is not applied and continued, a conical stump is produced with projecting bare bone covered with a wide area of granulation tissue below the retracted skin margin several inches above the end

of the bone. The soft tissues become fixed, circulation is cut off below, the bone becomes infected and the soft tissues frequently cannot be even partially pulled down by the late application of traction. Plastic resection with further bone shortening will be necessary for closure.

If the patient is to be evacuated, traction may be maintained by the application of a Thomas or an Army half ring splint and elastic fixed traction to the splint end. The stump is secured to the side bars of the splint by bandaging.

The primary (immediate) amputation may be necessitated by destruction of circulation to all or to part of an extremity, for the control of hemorrhage or to remove a hopelessly destroyed extremity or one which has been pinned down or crushed by falling masonry or a heavy weight before fluid becomes lost through dilated capillaries or absorption of toxic products occurs. A traumatic amputation may have occurred and only a debridement of the remaining extremity may be required, or it may be necessary to sever only a few remaining strands of muscle or skin with a snip of bandage scissors.

Fig. 5—Same stump as in figure 4 twelve days later. Traction that was begun at the time of amputation is being continued. The adhesive traction may be seen rolled back.

The secondary (delayed) amputation may be necessary several hours or days after injury, the usual indication being infection, gas gangrene, a septic joint, chronic osteomyelitis, recurrent uncontrollable hemorrhage or gangrene from destroyed circulation.

SITE OF AMPUTATION

The site of amputation should be the lowest level possible, regardless of the utility of the stump. If amputation is indicated in an extremity in which a compound fracture has occurred, the proximal fragment of the fracture should represent the "saw line" if sufficient soft tissues survived the injury to accomplish this. Amputation above this level is a useless sacrifice of bone length unless a higher site is necessitated.

In the secondary or delayed guillotine, the saw line should be as low as is consistent with saving the patient's life and removing the focus of infection. This is usually a question of surgical judgment. I have repeatedly obtained positive cultures of Welch's bacillus from the tissues of a guillotine stump after amputation at the site of a compound fracture without further progress of the disease occurring. The stump end is wide open, affording ideal drainage. The medullary canal of the bone

end early becomes sealed by the formation of internal callus and the bone becomes covered by granulation tissue

The closed method of amputation is not believed to have any place in the treatment of battle casualties or in amputation for the control of infection. In late primary amputations, and always in the delayed, infection too often is already established in the lymphatic glands above the lesion, and primary closure is done with great hazard

THE REPAIR OF THE GUILLOTINE STUMP

The flapless guillotine method is a two stage amputation. This really should not be a cause for its rejection, because the repair of the properly treated guillotine stump is ordinarily a minor procedure

PLASTIC CLOSURE

In the healing of the stump, the muscle and fascia have become fixed to the stump end, and the closure of muscle and fascia is not necessary as in a primary amputation. The scar tissue at the stump end is excised *en masse* through healthy skin and dissected from the fascia and muscle to the bone. If the scar is adherent to the bone end, $\frac{1}{8}$ inch of bone is excised by a saw. A plastic closure is then accomplished by undercutting the skin from the fascia, advantage being taken of its elasticity, and the suture line is allowed to fall where it will

PLASTIC RESECTION

If skin traction has not been properly carried out after the primary amputation, the soft tissues will be retracted, the bone end may extend 3 to 4 inches beyond the retracted skin in a thigh stump. Further bone shortening is necessary for repair. The scar tissue is excised *en masse*, bone is resected sufficiently to permit a skin closure. The wound is closed as in the plastic closure

REAMPUTATION

If the stump is too long, i. e. through the tarsus, lower third of the leg or at the wrist, a reamputation is indicated at Syme's level, the middle third of the leg or at the site of election in the forearm. If the stump is too short i. e. the upper third of the leg or the upper third of the forearm, reamputation is indicated at the site of election in the thigh or arm. Here the classic primary closed flap method is used

Secondary closure of the circular guillotine stump is a wasteful procedure, as further bone shortening will be required, since a closure of skin, fascia and muscle is necessary. The repair should be delayed until a plastic closure is possible, unless the stump is too long

Before the guillotine stump is repaired x-ray examination should show no infection or sequestration in the bone end, the granulation tissue should appear healthy, cultures should show the absence of streptococcal infection and the soft tissues should show an absence of inflammatory edema

Fig 7—Same stump as in figure 5 ten days later. Clean granulation with no edema twenty eight days after amputation. The wound will soon be ready for plastic closure. X-ray examination showed no abnormality of the bone

Sulfanilamide or sulfathiazole should be used freely under the skin flaps before closure. With the use of these drugs it has already been shown that these stumps may safely be closed much earlier without fear of infection than during World War I

SUMMARY

1 The circular or flapless guillotine method is the simplest, quickest and easiest method of amputation conditions which are essential in a badly shocked or critically ill patient

2 The patient becomes transportable earlier without the fear of the disastrous result of infection, which too often follows the closed method

3 It exposes less soft tissue area and affords adequate draining of infected bone and the closed muscle fascia spaces of the extremity thus limiting infection by adequate drainage

4 It affords a stump of maximum bone length that survived the original injury

Army General Hospital

ABSTRACT OF DISCUSSION

DR VERNON P THOMPSON, Los Angeles. As a civilian without military experience, I am glad that while taking care of my share of two thousand amputations the last fifteen years at the Los Angeles County Hospital I had been a pupil of Dr Philip Wilson and was aware of the importance of these essential principles which Dr Kirk has laid down. We have all seen examples of the failure to preserve adequate soft tissue to cover bone in amputations. It is necessary to bear in mind precisely what type of patient Dr Kirk has described and not confuse this problem with elective procedures or urgent amputations under good conditions. Even in these instances I prefer the stepped circular technique to flap procedures. The traction strips need to be applied properly close to the line of amputation, the circular strip not to be so tight as to act as a venous tourniquet causing swelling and trouble in healing of the amputation stump. Once the skin and superficial fascia are distal to the bone end, the contraction of the maturing granulation tissue healing the amputation site is a material factor

Fig 6—The difficulty in treating a stump with diluted solution of sodium hypochlorite is in placing individual tubes in position and keeping them there. Carrel tubes may be prepared in proper length in advance, sutured to several thicknesses of gauze the size of the stump end sterilized and be made available before amputation and for future dressings (Amputations, Lewis's Practice of Surgery, 1)

in closing the wound. When the surgeon assists slightly in the retraction of each layer of skin, superficial fascia and muscle, a considerable number of the circular amputations at the knee level, cutting the femur close to a flare in the condyles, heal primarily with a small posterior scar without any secondary closure. Yesterday Dr. Wallis told us something about what happens to devitalized tissue, pointing out that even with such a clear, clean procedure as Colonel Kirk described it will not make up entirely for the lack of gentleness by the surgeon in removing the part.

DR. LYMAN W. CROSSMAN, New York: We are much interested in refrigeration anesthesia for all amputations and we have had startling success. I am sorry that Dr. Wilson isn't here, because we introduced it in his hospital. With the refrigeration anesthesia the patient has no shock during the operation or afterward, and they have no bleeding at the time of the operation. Because we use refrigeration, by means of cracked ice or by means of a refrigerator that can be run in the ambulance on the same generator that runs the electricity for the lights, we can keep down the swelling and while we cannot overcome the infection we can control it as long as the refrigeration is on. All our cases have been done by means of a circular incision on the oblique so that when the part heals, if it happens to be a clean case the healing shows the scar definitely posterior. We do have fulminating infections in a large municipal institution, probably, that compare with any war infection, and as a result of this particular technique we welcome the most fulminating of the infections.

DR. EDWIN W. RYERSON, Chicago: In the preceding war we were instructed to perform amputations according to the method of Bunge, detaching a narrow strip of periosteum from the end of the bone. Dr. Kirk now does not approve of this. There is a tendency at the present time among neurovascular surgeons to omit the injection of alcohol into the end of the nerve. I have performed many amputations using the alcohol injection and up to this time have seen no evidence of the formation of a painful neuroma. I believe that the alcohol injection should be made standard in the present war.

DR. NORMAN T. KIRK, Washington, D. C.: Dr. Thompson and I are apparently in perfect agreement. The soft tissues need a bit of help in their retraction as each layer is cut through. I have had no experience with the refrigeration of extremities. This method of anesthesia in certain selected cases has been ideal and Dr. Crossman is to be congratulated on his work. I doubt if this method will be applicable under war conditions. It might be used in late cases in the general hospital. Dr. Ryerson speaks of the removal of a cuff of periosteum. This is always done in the closed type amputation but never in the open method. If periosteum is removed when the guillotine amputation is performed a ring sequestrum of the bone end invariably occurs. The normal periosteum covering the bone very definitely prevents infection therein. A long discussion might be entered into on osteoplastic methods. It was once thought that the uncovered bone in a stump caused a painful stump. Therefore certain osteoplastic procedures were evolved. The bone end was covered either with periosteum or with bone, examples being the Gritti-Stokes method. This of course, was true as Bunge demonstrated when he showed that the bone end from which a cuff of periosteum was removed produced a nonpainful stump.

Withering and Dehydration.—Old age has always been regarded as a period of withering and dehydration. The progressive loss of water is most conspicuous in those structures which are normally poorly vascular, such as cartilage and the lens of the eye. The tendency to water loss, however, is universal, and loss of intracellular protoplasmic fluids may be considered characteristic of senility. From this stems a trend to transform the condition of a sol to that of a gel to condense the older tissues and to impair the ability of body fluids to keep substances in solution. This favors the precipitation of such substances as calcium salts, cholesterol and pigments.—Mueller-Deham, Albert, and Rabson. *S. Milton. Internal Medicine in Old Age*, Baltimore, Williams & Wilkins Company, 1942.

STUDIES ON METHODS OF PREVENTION OF EPIDEMIC INFLUENZA

JOSEPH STOKES, JR., M.D.

AND

WERNER HENLE, M.D.

PHILADELPHIA

The control of any epidemic respiratory disease in time of war, when aggregations of individuals are rapidly changing in both position and size, is a challenge to preventive medicine. For such a disease as epidemic influenza, in which possible methods of prevention during peacetime have been gaining a properly controlled momentum, the acceleration required by the war may well advance the consideration of preventive measures which, though evidence is not complete, have sufficient experimental success to warrant trial. Obviously, such trials should include only those measures which from previous experimental observations have the greatest possibility of success and which have at the same time no deleterious effect.

Despite the large group of respiratory infections of different etiology which resemble epidemic influenza, it has been possible since 1933 to identify widespread epidemics of influenza type A¹ with some degree of clarity. The virus of influenza type B has been more recently identified (in 1940)² and epidemics originating from it apparently have been small and scattered although this may not continue to be true. In addition it has been possible in most of the epidemics of influenza A to predict the spread geographically to some extent. Moreover, epidemics of influenza A have followed alternate years with considerable regularity since 1933, occurring successively in 1935, 1937, 1939 and 1941. Such regularity of appearance and spread should be utilized in the consideration of preventive measures, combined with the realization that irregularities in sequence, spread and especially in etiology may increase in the future. Confusion concerning the etiology of certain epidemics of respiratory disease should not hinder active prophylactic measures against those which are to a great extent recognizable, and in the present critical period the adage may well be applied to epidemic influenza that often the most dangerous experiment of all is to do nothing.

The discussion of prophylactic measures against both influenza A and B may be divided into three main categories: (a) measures for the control of air borne infection, (b) vaccination procedures and (c) the use of immune serum.

MEASURES FOR THE CONTROL OF AIR BORNE INFECTION

It has been demonstrated experimentally that the virus of influenza A can be transmitted to animals by the air borne route,³ and it is in all probability by this

route that the epidemic spread occurs. Methods for the disinfection of air are therefore important in any consideration of the control of epidemics.

Thus far two important agents have been used experimentally in animals and man for such disinfection: (1) ultraviolet rays and (2) propylene glycol vapor.

Ultraviolet Irradiation of Air—Although the bactericidal action of sunlight and ultraviolet light was known for many years, irradiation was not applied to the practical problems of air disinfection until rather recently in the work of Wells⁴ and Hart.⁵ Their studies were assisted considerably by the development of methods for determining quantitatively the contamination of the air by micro-organisms. In the course of such studies it has been found that air borne influenza virus type A can be destroyed by such irradiation⁶ and further that infection of mice with influenza A virus by the air borne route can be prevented by suitable irradiation of the inhaled air laden with virus.⁷

The Use of Propylene Glycol Vapor—The usefulness of propylene glycol vapor for the disinfection of air was first fully recognized by Robertson and his associates,⁸ although English workers⁹ had noted the increased effectiveness of disinfecting aerosols such as hexylresorcinol when propylene glycol was used as a vehicle. This substance, like ultraviolet irradiation, was found to be highly effective in the prevention of the air borne transmission of influenza A virus to mice.¹⁰

In this pediatric clinic¹¹ experimental comparisons of these two methods for disinfection of air have been made in a large enclosed space which closely simulated field conditions. For this purpose a large infant ward was chosen at a time in the early fall when it was not needed for patients. The ward is approximately 47 feet by 27 feet by 11 feet and is divided as shown in figure 1 into sixteen cubicles open in front and separated from one another by walls reaching from the floor to within 4 feet of the ceiling. The arrangement for irradiation previously described¹² provided a curtain of ultraviolet light in front of each cubicle and a complete irradiation of the entire upper portion of the room above the tops of the cubicles. Propylene glycol was vaporized to a concentration in air of approximately 1,200,000 to 1,400,000 from an electric hot-plate placed in front of an electric fan in the position shown in figure 1. For both disinfecting agents as well as for the study of this space under control conditions the doors and windows remained closed, and highly mouse virulent

suspensions (allantoic fluid) of influenza A virus were atomized into the air. Cages, each containing 10 mice, were placed on bed frames close to the back wall of the seven cubicles indicated in figure 1. The experiment consisted of three periods in which the virus was atomized, each of one hundred and fifty minutes. During the first period the ultraviolet light was tested; during the second period no agent was used for control; and during the third period propylene glycol was vaporized. Between the second and third periods the ultraviolet lights were used to sterilize the air and propylene glycol was vaporized for thirty minutes in order to insure a sufficient concentration of vapor before the exposure of the third group of mice.

Table 1 shows the results obtained in mice in the three periods described. It may be noted that all 70 of the control mice died within ten days from such exposure.

Fig 1—Floor plan of infants ward

with typical influenzal lesions, whereas with the ultraviolet light only 3 of the 70 mice died. All 3 of these were of the group placed in the cubicle containing the atomizer, while the other mice in the same cubicle at autopsy on the tenth day showed varying degrees of pulmonary consolidation. In the two cubicles adjacent to the atomizer, 12 additional mice at autopsy showed slight pulmonary involvement while all the remaining mice had no lesions. On the other hand when propylene glycol was used all mice survived and only 3 animals in the cubicle containing the atomizer showed influenzal lesions at autopsy on the tenth day, none of the other mice showed any apparent signs of influenza. Three other mice died from noninfluenzal causes.

In summary of these experiments it may be stated that ultraviolet irradiation and propylene glycol vapor in the proportions used were almost equally effective in preventing air borne infection of mice by influenza A virus.

The use of ultraviolet light in clinics and elsewhere has received many experimental trials, as reported by numerous investigators,¹³ with encouraging results in many instances. On the other hand, the application of propylene glycol vapor has progressed little beyond the stage of animal experimentation. Here also, however, a small preliminary study starting Jan 1, 1942 has given results suggestive of its value in the prevention of

human respiratory infections other than influenza. This study was carried out by Dr T N Harris¹⁴ from this pediatric clinic in two comparable wards of 16 patients each in a convalescent home for children. The incidence of respiratory infections of all types in the two wards, under ordinary conditions, was approximately equal from Jan 1, 1942 to Feb 22, 1942 (15 and 16 cases respectively). Following the vaporization of propylene glycol, starting on Feb 22, 1942 in the experimental ward in a concentration of approximately 1 30,000,000 to 1 40,000,000,¹⁵ the incidence of respiratory infection over the period from Feb 22 to April 18, 1942 in the experimental ward fell to a single questionable case and 1 case which occurred two days after onset of vaporization. The incidence in the control ward for this period, on the other hand, remained the same (16 cases). As soon as vaporization of the propylene glycol was discontinued respiratory infections again returned to the experimental ward.

15 This concentration was determined by the method of Fack (Science 95: 178 [Feb 13] 1942) and was sufficient to reduce the number of air borne organism in the ward very considerably

VACCINATION PROCEDURES

Vaccination of human volunteers against influenza A was first attempted as early as 1935,¹⁶ and the first results indicating the partial effectiveness of such a procedure in reducing the incidence of influenza A were reported from this laboratory.¹⁷ Active virus from mouse lung suspensions and chick tissue cultures were used at first but were abandoned later in favor of somewhat safer¹⁸ and more concentrated preparations. The high concentrations of virus in chick embryonic fluids were first observed with swine influenza virus¹⁹ and were subsequently noted in human influenza A.²⁰ Studies on the vaccination of mice with such fluids gave excellent results,²¹ and results of vaccination of human beings with such fluids were quite successful as far as the antibody response was concerned.²² In this laboratory such fluids, inactivated by solution of formaldehyde, have been used extensively for studies on vaccination during the past winter in two state colonies in New Jersey.²³ Three groups of approximately 100 individuals each were vaccinated either by a single intramuscular injection (3 cc of a mixture of strains PR-8, WS and of Melbourne influenza A) or by three such doses at weekly intervals or one intramuscular injection and two inhalations of inactivated vaccine a week apart. In other smaller groups, mixtures of the PR-8 strain of influenza A and the Lee strain of B were used, or either one alone. A satisfactory antibody response was noted in all groups as measured by the technique of Hirst (inhibition of chick red cell agglutination) and the results were closely comparable to those reported by his group.²⁴ There was no difference in antibody response in the groups treated by single or multiple injections.

A more critical test of the protective value of this inactivated allantoic fluid vaccine was then conducted in a single cottage housing 72 boys, namely 44 vaccinated and 28 unvaccinated controls. The 44 boys had been vaccinated partly in December (PR-8, WS, Melbourne) 1941 and partly in March 1942 (PR-8 only). In April 1942 all individuals were permitted for four minutes to inhale through aviation oxygen masks atomized allantoic fluid (approximately 0.4 cc each) containing a strain of influenza A virus (F-99) freshly isolated from an infant which died with an overwhelm-

ing influenzal infection early in 1941. Table 2 shows the striking incidence of clinical influenza in the control group as compared to the single case in the vaccinated group, despite the greater number of individuals in the vaccinated group. There existed an inverse relationship between the amount of serum antibodies and the incidence of clinical influenza in these groups. It should be noted that the single case of clinical influenza in the vaccinated group had shown little, if any, response to the vaccine, showing very few antibodies in the blood serum immediately before inhalation of the active virus F-99. This inverse relationship was demonstrated originally by Smorodintseff and his co-workers and others,²⁶ as were also the clinical course of experimental influenza in human beings and the alterations in the total and differential white cell counts, although none of the volunteers in the previous studies had been vaccinated. A sulfonamide drug was administered in the present study to all patients with clinical influenza for protection against secondary bacterial complications, of which there were none. Figure 2 indicates the febrile course and white cell changes in 1 of the typical cases of influenza. The diagnosis of clinical influenza was made in all cases in which the temperatures were over 100 F and the clinical signs and symptoms justified such a criterion. Flushing of the face, malaise, dryness and redness of the throat, aching of the back, arms and legs and dry cough were the outstanding signs and symptoms. There was little nasal discharge, no hoarseness and rales were usually absent from the chest. The virus was reisolated in a number of cases on the second or third day after the inhalation and all cases showed pronounced rises in neutralizing and complement fixing antibodies to the PR-8 strain of influenza A. The illness, as shown, was short and not severely disabling nor was the convalescence a long one.

Although clinical influenza was, on the whole, absent from the vaccinated group, subclinical infection undoubtedly occurred, since a high percentage of boys in the two groups showed temperatures of 99 F or over dur-

well as in the control individuals, but it was noted that a significantly larger number of leukopenias occurred in the latter. The leukopenias were not necessarily related to temperature or titer of antibodies before inhalation. No other signs were noted in these groups, and the boys felt well.

This investigation, favorable as it is to the value of vaccination against influenza virus A, should lend

Fig. 2—Influenza following inhalation of active virus

encouragement to the further study of widespread vaccination under war conditions. It is possible that the partial protection afforded in the past against influenza A by various vaccines may be improved by the use of the more highly concentrated virus obtainable from the egg fluid, as utilized in these experiments.

Although no clinical trials under epidemic conditions have been as yet possible with influenza virus type B, studies conducted on mice and on human beings in this laboratory are confirmatory of those reported by Eaton and his co-workers, namely that pronounced rises in antibodies occur following vaccination with the inactive virus of influenza B. A combination of a concentrated virus vaccine containing both viruses A and B is now being used here and elsewhere in studies concerning their protective value.

THE USE OF IMMUNE SERUM

The use of serum containing large amounts of immune bodies against influenza virus A for passive immunization by means of inhalation was first reported by Stokes and Shaw,²⁷ and later by Smorodintseff²⁸ and others who also mentioned briefly the experimental use of such serum in the treatment of influenza A. Later more extensive studies²⁶ have fully confirmed the value of

ing the week of the experiment, particularly on the second and fourth days after inhalation of the active virus. The subclinical infections, as indicated in general by the term, were selected only by the criterion of a temperature between 99 and 100 F. A large number of leukopenias were noted in the vaccinated group as

such immune serum for passive immunization of mice by inhalation and also for use in mice even twenty-four to forty-eight hours after the intranasal inoculation of the virus. Such a study is shown in table 3 and indicates the relatively small amounts of immune serum required for protection of the mice when serum is inhaled as compared to the amount required by the intravenous or intraperitoneal route for the same degree of protection.

The results of such passive immunization by inhalation in ferrets have not been as striking, although a pronounced decrease in lung involvement of the ferret can be effected by this method of inhalation. From recent experience it is probable that better methods of atomizing the serum and of inhalation may increase the effectiveness of this method.

The collection and preservation of large amounts of immune serum from convalescent or from vaccinated individuals has been of assistance in the experimental trial of such methods of passive immunization and also of treatment under natural field conditions. In this regard, studies have recently been carried out in this laboratory on the globulin fractions of pooled adult plasma furnished by Dr. Edwin Cohn, according to his method of plasma fractionation. The concentration and preparation of antibodies by this method should aid considerably in passive immunization of animals and also possibly of human beings and should aid in a similar experimental approach to the therapy of the disease under field conditions.

SUMMARY AND CONCLUSIONS

Experimental evidence was obtained concerning three promising approaches to the control of epidemic influenza and in particular influenza A, namely (1) by disinfecting within enclosed spaces the vehicle, air, through which cross infections probably occur (2) by actively immunizing susceptibles and (3) by passively immunizing exposed susceptibles with immune serum.

1. Studies were made concerning the comparative merits of ultraviolet light and propylene glycol vapor for disinfecting the air of influenza A virus and concerning the possible protection of individuals from cross respiratory infections by means of propylene glycol vapor.

2. A group of boys vaccinated against influenza A virus and a group of suitable controls were exposed to a recently isolated active influenza A virus by inhalation. Striking protection was afforded by the vaccine.

1740 Barnbridge Street

ABSTRACT OF DISCUSSION

DR. ALBERT B. SABIN, Cincinnati. It is a very difficult task even to attempt to substitute for Dr. Trask, who was scheduled to open the discussion and whose loss is felt not only by all of you but by many others in many related fields. The work presented this morning by Drs. Stokes and Henle shows that a number of hopeful procedures are available for trial during an epidemic of influenza. The experimental work of Drs. Stokes and Henle differs from that of many other investigators of influenza in that it is not limited to mice. There is truly a story of mice and men. It is amazing the way Dr. Stokes manages to carry out experiments under excellently controlled conditions in human beings, in a way that gives us information that could hardly be obtained in the field during an epidemic. If he told us nothing more this morning than the story of that excellent experiment on some 70 odd individuals who were divided into vaccinated and nonvaccinated groups and then artificially infected with the virus under carefully controlled conditions, it would indeed be a landmark in the work on influenza.

He probably could have spent a great deal more time describing the syndrome resulting from experimental infection of human beings with influenza virus. The evidence presented leaves little doubt that very striking protection can be obtained against one type of influenza virus by vaccination at the appropriate time. To be sure, the great difficulty is that in epidemics of influenza the incidence of various immunologic types of the virus is unpredictable and the total number of cases that may be prevented by vaccination against one or even two types of the virus may by itself perhaps not stop the course of the epidemic. However, particularly during times of war, the protection of even 30 or 40 per cent of a large population against influenza would be a distinctly worthwhile accomplishment. The evidence that ultraviolet radiation and propylene glycol may be expected to destroy some of the virus in barracks or in other crowded places that vaccination may protect some if not all, and, finally, the experiments on animals indicating that the insufflation or nasal instillation of anti-influenza serum may also protect all lead to the realization that tools are available for the attempt to modify the course of an influenza epidemic.

DR. E. C. ROSENOW, Rochester, Minn. I wish to compliment Drs. Stokes and Henle on their excellent work, especially on the emphasis which they place on the need for preventing air-borne infection. In order to emphasize the importance of air-borne infection in influenza and other epidemic diseases and the reason for their occurrence may I state briefly the results of certain bacteriologic studies made of indoor and outdoor air by special methods with which we have isolated consistently pneumotropic types of streptococci from and have demonstrated influenza streptococcus antigen by the precipitation reaction in washings of air of rooms occupied by persons having influenza and other respiratory infections and during epidemics from washings of outdoor air and from rain. Recently this streptococcus has been isolated from and the antigen demonstrated in newly fallen snow, after a prolonged spell of dry, cold, clear weather. This snowfall occurred on Feb. 8, 1942 at the outset of an epidemic of influenza. The streptococcus was isolated from four widely separated samplings, including two in the country far removed from human habitation. It had extreme pneumotropic virulence producing hemorrhagic edema and bronchopneumonia on intracerebral inoculation of rabbits of extremely small doses and on intranasal inoculation in mice. This was true of the primary culture and of cultures far removed from the original source. Interestingly, emulsions and filtrates of the pneumonic lungs of mice that had been inoculated with cultures of the streptococcus far removed from the original source produced bronchopneumonia in mice on intranasal inoculation. This virus derived from the streptococcus was then passed successively in series on intranasal inoculation through fifteen mouse passages. Cultures from the pneumonic lungs were usually negative, but the streptococcus identical morphologically and antigenically to the streptococcus isolated from the snow was isolated in cycles of from three to nine mouse passages. This and other similar experiences suggest strongly a relationship between the streptococcus-pneumonia group of organisms so commonly at hand in pandemic, epidemic and endemic influenza and the virus of influenza. Attempts to isolate pneumotropic or influenza virus from the snow proved unsuccessful. The general presence for reasons still obscure, of certain specifically virulent streptococci and streptococcus antigen characteristic of epidemics is believed to be of epidemiologic importance and needs to be considered in their control. Specific, active immunization, in advance of or abreast with epidemics, with appropriate vaccines or antigens is specially indicated.

DR. JOSEPH STOKES, JR., Philadelphia. We appreciate Dr. Sabin's remarks and agree thoroughly with him that there are difficult problems in epidemic influenza as far as the etiology of the epidemics is concerned. Simple methods such as the inhibition of red cell agglutination as developed by Hirst for the determination of neutralizing antibodies should assist considerably in the analysis of epidemics of influenza and the effect of vaccination. A proper comparison of various results on vaccination cannot be made unless one knows the type and strength of vaccine, the method of vaccination and the length of time after vaccination that the epidemic occurs.

WHAT CAUSES FLATULENCE?

WALTER C. ALVAREZ, M.D.

ROCHESTER, MINN.

Flatulence is one of the commonest symptoms complained of by patients with indigestion or what they think is indigestion. Unfortunately, in many cases the cause cannot be determined. The first thing the physician must do when a patient complains of gas is to find out what he means. Does he mean that he is belching, does he bloat, does he feel as if gas was trapped in a segment of intestine or does he pass excessive amounts of flatus? Curiously a patient may have any or all of these troubles and still not have real flatulent indigestion! The chronic belcher is swallowing air because he is nervous or frightened, the woman who bloats may have only an angioneurotic edema of her bowel, the man who feels as if he had gas in his stomach may have only a duodenal ulcer or constipation, and the man who is passing much flatus may only be chewing gum and swallowing much air with the saliva.

THE PATHOLOGIC PHYSIOLOGY OF FLATULENCE

Before taking up the clinical aspects of flatulence, I will speak briefly of the mechanisms by which gas gets into and out of the bowel. Contrary to the common impression, most of the gas is probably not formed through fermentation in the bowel. Analyses have shown that most of it is nitrogen left from swallowed air. Some persons swallow much air, but just why, no one knows. Perhaps when they swallow fluids they do not close their lips over the glass, or in them the muscles of the tongue and nasopharynx behave peculiarly. Every one, of course, swallows some air with "raised" breadstuffs. Because nitrogen is not easily absorbed from the bowel, nearly all of that which is swallowed in air must go on through to the rectum to be extruded as flatus.

Often, when a person feels that he is distended with gas, roentgenologic examination of the abdomen would show that he is mistaken. In adults there is usually little gas to be seen in the small bowel. What gas there is in the abdomen is generally in the colon. This may be due to the greater ability of the small bowel either to absorb gases or to pass them on rapidly. Some of the gas in the intestine is apparently excreted from the blood. Under the influence of emotion, such excretion can take place with surprising rapidity.

Flatus does not contain much carbon dioxide or oxygen, because these gases are easily and rapidly absorbed by the bowel and thrown out through the lungs. In herbivorous animals large amounts of gas are constantly being taken up by the blood as it passes through the walls of the stomach and cecum. Obviously, any condition that interferes with the return of venous blood from the intestine is likely to produce gaseous distention. Pneumonia, which interferes with the passage of gases from the lung, can also produce intestinal distention. As Fine has shown, when a man with a bloated abdomen is made to breathe pure oxygen, there is such a steepening of the gradient in nitrogen tension from the intestine through the blood to the alveoli of the lungs that the gas rapidly leaves the distended bowel.

Swallowed air usually is passed through a normal bowel easily and rapidly and painlessly, but gas resulting

from the eating of some food to which the patient is allergically sensitive seems often to remain trapped for hours in segments of bowel which are tonically and painfully contracted. Relief comes only when perhaps, with the taking of food, waves again start traveling down the bowel. When the Emperor Claudius, who suffered from flatulence, published an edict that no Roman need feel reticent about passing flatus in public, one of his waggish courtiers suggested that while he was at it he should have passed another law to enable every Roman to pass gas whenever it was distressing him!

BELCHING

An ordinary single "burp" is due usually to a reverse wave coming up the esophagus from an overfull stomach, but repeated belching is due always to the swallowing of air. This goes down as far as the cardia and is then returned. Roentgenologic studies show that only occasionally is some of it forced into the stomach. When a man belches repeatedly in this way it is usually because he is trying to relieve a feeling of distress about the cardia, which I am sure is due often to the running backward of waves on the stomach. He may keep on belching for ten minutes or more, hoping that eventually he will get up one huge belch which will delight him and put an end to his distress. This big belch can be gotten sometimes by drinking a little sodium bicarbonate in water. I think what happens then is that the reverse waves stop running, and the man feels relieved just as he would if an attack of auricular fibrillation was suddenly to stop.

It isn't enough to tell a patient that he is swallowing air and should stop it. To be sure, an intelligent and strong willed person, when he is convinced that he is, in a way, just scratching himself with air and developing a useless and unpleasant habit, will usually stop. But even then the physician should go ahead to find out why the man got to swallowing air. Sometimes it is just a nervous habit, like a tic or the cracking of knuckles which some ignorant persons indulge in when nervous and ill at ease. Many persons belch because they are so terribly on edge, with the knee jerks exaggerated. Others start belching when they are frightened, perhaps by a feeling that the heart is failing or that some undefinable disaster is impending. Business men may belch at night when they are under great strain and fearful that they are going to crack up nervously.

Many men and women wake in the night frightened, perhaps by an extrasystole, and this starts them to belching. In such cases the main factors are jitteriness and fear of heart trouble, and no treatment can succeed until the patient is reassured. In other cases, and especially with elderly men, the heart is actually failing under the influence of hypertension or coronary disease, and this is what is producing the distress around the cardia. In a few cases the gas that the man is trying to get rid of is in the splenic flexure of the colon. Naturally, then, it cannot be gotten up, no matter how long the man belches. Not infrequently the disease at fault is in the gallbladder.

Occasionally one finds a particularly expert and noisy belcher who is a near relative of the insane, and his attacks are then due to sudden panicky spells, due perhaps to a fear that he is losing his reason.

BLOATING

When a woman bloats, much can be learned about the cause by questioning her. Has she noticed that the distention follows the eating of any particular foods

or does it follow excitement or strain or fatigue? How does the swelling go down? Is gas passed then or isn't it? If no gas is passed, then the bloating is likely to be of the type that is due perhaps to angioneurotic edema of the intestine or an abnormal concentration of blood in the abdomen. In these cases roentgenologic studies show that it is not due to gas in the bowel. Usually this type of bloating is found in a nervous woman who is crossed in love. The swelling increases during the day and generally goes down during the night. With it there may or may not be discomfort, indigestion or constipation. Naturally, in such cases enemas and carminatives do not help. A patient with true bloating due to gas will get relief as soon as the gas is passed.

Curiously, some persons bloat suddenly the minute they drink a glass of water or put any ice cold fluid into an empty stomach. In these cases it would seem that there must be some reflex disturbance which causes gas to pour from the blood into the bowel.

A FALSE FEELING OF FLATUS

A few patients with duodenal ulcer and many with "pseudo ulcer" will complain not of hunger pain but of a feeling of gaseous distention which is usually relieved shortly after the taking of food. What happens probably is that the food causes gas to move on out of some segment of the bowel. It starts waves going normally down the intestine. Constipation is a common cause of such distress because the plug in the rectum tends to hold back the waves which would otherwise move the gas onward.

EXCESSIVE FLATUS

Persons with an excessive amount of flatus must be swallowing much air or else they are suffering with much intestinal fermentation or with some breakdown in or reversal of the mechanism by which the blood normally carries gases out of the bowel. In disease these gases can be excreted from the blood into the bowel. Flatus which has no odor is likely to consist of air, while that which is foul is likely to be produced through the fermentation of food. A bad odor can, however, be picked up by the gas as it is churned with feces and particularly with liquid feces. Particularly foul flatus is due sometimes to the eating of some food to which the patient is allergic.

CONSTIPATION

Probably one of the commonest causes of flatulence is constipation. The physician should always ask whether the flatulence disappears when the bowels get to moving normally. It helps diagnostically to have the patient take an enema of a quart of isotonic solution of sodium chloride every day for a few days to see if this works a cure. In some persons the taking of laxatives of any kind will produce flatulence. In case the colon is sensitive, even a small mass of fecal material in the rectum may for hours cause gas to keep forming. That the mechanism at fault is a nervous one is indicated by the fact that the minute the fecal mass is expelled the gas will stop forming.

THE EATING OF CERTAIN FOODS

As Hippocrates noted ages ago, and as the peoples of Europe have discovered during the two world wars, a rough diet can be flatulent and windy. There are many persons with a sensitive bowel who cannot handle much roughage. As this irritates the mucosa, it perhaps interferes with the normal passage of gas out of

the bowel, or its presence interferes with the digestion and absorption of carbohydrates. As every one knows, some foods, such as dried beans and cooked cabbage, are particularly likely to produce flatulence. Evidently they contain some chemical substance which irritates the mucosa of the bowel and interferes with the passage of gas through it and into the blood.

Curiously, on questioning 500 patients as to the foods that actually gave them gaseous distress, Hinshaw and I found that most of the persons complained of onions. Next, in order of frequency, the foods most commonly blamed were cooked cabbage, raw apples, radishes, dried beans, cucumbers, milk, fatty or rich foods, melons, cauliflower, chocolate, coffee, lettuce, peanuts, eggs, oranges, tomatoes and strawberries.

FOOD ALLERGY

Probably more commonly than physicians suspect today, flatulence is due to the eating of some food or foods to which the patient is allergically sensitive. The result often is abdominal distention and crampy pain. The important point to remember is that some of the worst gas producers are not the notoriously indigestible foods but those such as milk and eggs, which have a fine reputation in the sickroom. Actually, any food can be the offender, and it can be identified and incriminated only with the help of some detective work. Sometimes the patient can discover it by keeping a record of unusual foods eaten a few hours before the bloating appears. Occasionally, some drink such as rum will irritate a sensitive colon and cause flatulence.

OVEREATING

Commonly, an attack of flatulence follows the eating of so much food that the bowel becomes overwhelmed and cannot handle it all. Then some of it ferments and decomposes, and the bowel fills with gas.

ANXIETY OR PAIN

In some persons gas appears rapidly in the bowel under the influence of pain, fear or excitement. Dr. Stafford Warren once pointed out to me that the first film made of a sensitive patient just before he submits to the passage of ureteral catheters usually shows but little gas, whereas the second film, made after the catheters are in place, often shows the small bowel filled with gas.

CHOLECYSTITIS

A common cause of flatulence or bloating or a feeling of flatulence, especially in stout women past middle age, is cholecystitis. Just what the mechanism is which produces the distress is not known. In these cases it often helps if the patient eats less and particularly if she eats a light supper.

COLDS

Some persons with a sensitive bowel suffer from gas when they are coming down with a cold. The virus appears to work some injury to the bowel because often the worst part of the intestinal upset comes during the prodromal period, when as yet there is no disturbance in the nose, throat or lung. Perhaps some mucosal change appears in the bowel before it appears in the nose and throat.

DIARRHEA

Many persons with diarrhea are plagued by flatulence which may be due to a defect in the absorptive functions of the mucosa of the small bowel, related to that which has led to a decrease in the absorption of water and residues from the digestion of foods. Per-

haps also the cause of the diarrhea interferes with the mechanism that causes gas to pass through the mucosa and into the blood vessels of the intestine

A SENSITIVE COLON

Many patients with a sensitive, mucus forming type of colon suffer with gas. This may form when the patient goes out to dinner or to the theater, or perhaps when he entertains in his home. The trouble seems to be due partly to excitement and partly to a vicious circle which starts when a little gas forms and cannot, for reasons of politeness, be passed immediately. The distention of the rectum then causes more gas to be formed until the patient is in misery. That the trouble is due to nervous influences is suggested also by the fact that in some persons it can be blocked by the taking of a little paregoric or codeine.

HEMORRHOIDS

In some few persons flatulence appears to be due to the presence of irritated hemorrhoids or an inflamed and infected anal ring. The irritation around this ring seems to cause backpressure in the left side of the colon, and this causes gas to accumulate in the splenic flexure. Patients with a large amount of gas in the splenic flexure can secure some relief by getting into the knee-shoulder position or by hanging over the side of the bed so that the gas can rise up into the rectum and from there be expelled.

MILD INTESTINAL OBSTRUCTION

Whenever an older person who has never suffered with flatulence begins to note loud borborygmus, he should immediately have the bowel studied by a good roentgenologist and proctologist. I have seen a number of cases in which borborygmus was the first sign of the development of an obstruction due to a carcinoma of the bowel.

A FAILING HEART

As I have already remarked, especially in older men who have previously been well, the coming of flatulence after exercise, and particularly when the person walks after eating a meal, should make the physician think of a failing heart with some passive congestion in the bowel.

MILD CYCLIC INSANITY

Every so often a woman who comes complaining of gas is found to have a cyclothymic type of personality which causes her to be for a while too energetic and active and then for a while depressed, discouraged, irritable and tired out. She suffers with flatulence during the periods of depression.

INTESTINAL PARASITES

Since one of the possible causes of flatulence is infection of the bowel with parasites such as *Giardia* or *amebas*, in all puzzling cases of excessive flatus the stools should be examined by an expert.

TREATMENT

From what has gone before, it will be obvious that no one should ever attempt to treat flatulence without first finding out that the patient really has an extra amount of gas in his bowel. If actually there is some indigestion or an abnormal amount of gas present the next thing to do is to get some idea as to why it is there.

If the flatulence seems to be due to the eating of some irritating food, an effort should be made with the help of a food diary or an elimination diet to find out

what it is. The elimination of roughage, raw foods and some of the notoriously gas forming foods and laxatives may help, or the patient may get relief simply by cutting down on the amount of food eaten. The relief of constipation by enemas may give great relief.

Some of the persons who want to belch because they feel that they have gas in the stomach are helped by taking sodium bicarbonate, perhaps with some aromatic carminative added. It is hard to say how much good carminatives do or how they act. Alcohol sometimes works well and peppermint is probably helpful. In bad cases a teaspoon of camphorated tincture of opium often works best. Walking about is sometimes helpful because it starts the gas to moving down the bowel. Often the sipping of water or a little milk, or the taking of a little food will help by starting waves running down the intestine. When the gas starts to move out of the segment of intestine in which it has been trapped, the pain goes. When the gas is in the colon, relief can usually be obtained by the taking of an enema. Even when the gas is in the small bowel, an enema may bring relief by removing a plug of feces which is keeping waves from moving caudad. In some cases a diseased gallbladder must be removed, and in others a failing heart must be rested.

A friend of mine used to cure belching women by asking them if they were accustomed to pass flatus loudly in public. When, shocked and outraged, they said "Of course not," he asked why then were they so often passing it noisily by mouth!

ABSTRACT OF DISCUSSION

DR. BURRILL B. CROHN, New York. One should differentiate the complaint of gas when enunciated by the patient and when elicited by the doctor. The patient who talks of gas may cover any combination or syndrome of symptoms representing organic disease or functional subjective phenomena. Patients never know exactly what they mean by gas. They have no concept of gas as gas. Gas to the patient represents a discomfort, a pain, a mild colic, an audible rumbling or just a sense of heaviness or distress. So, when the patient says gas, one begins looking for flatulence due to disease. Gas may mean the beginning of carcinoma. Gas may mean the beginning symptoms of ulcer. Gas may be the first symptom of myocardial breakdown or the beginning of an onset of coronary disease. The most striking instance was illustrated by a German past middle age who belonged to a very reputable social club, played pinochle to 2 o'clock in the morning, ate heavy sandwiches and drank beer after 12:30 p.m. and then insisted on walking for 40 or more blocks. This man complained continually of gas, coronary disease was suspected because most of the distress took place on exertion after meals. The man died in a taxicab, he had complained only of gas. What the doctor hears with his ears and what he recognizes as gas are different things. The passing of audible flatus may be caused by anything from a continuous dietary indiscretion to a partial obstruction of the colon or disease elsewhere in the alimentary tract. Gas in the upper abdominal tract indicates myocardial or coronary disease, gas in the lower abdomen represents disturbed intestinal function. Gas may be created by the overeating of one particular article of food or by overeating in general. The patients themselves should know to what article of food they are susceptible—cabbage in one group of patients, cauliflower in another, cucumbers in a third. Each individual has a peculiar susceptibility. For these idiosyncrasies and peculiarities there are no natural cures. Overeating in kind or overeating in bulk is the cause for most of the lower abdominal gas. The treatment for this type of gas is semistarvation. Put them on a low diet, small meals slowly eaten, take out milk and most patients promptly lose gas. A patient with several abdominal scars in whom several surgeons have suspected and attempted to cure an intestinal obstruction should be suspected of hysteria and

adynamic ileus. The very sight of that huge abdomen should make one wary of surgery. This is another instance of the purest type of functional distention with gas.

DR. EDWARD WEISS, Philadelphia. I want to make one remark concerning anxiety in relation to gas. I suggest that you tell your patients what is in effect the truth, that the abdomen is the sounding board of the emotions and that when they are upset tea and toast will give them gas, and when they are at peace with themselves they can eat hardtack and digest it.

DR. WALTER C. ALVAREZ, Rochester, Minn. It is unfortunate that civilized man today has no intermediate words for certain bodily functions. As a result we are forced to use either the technical medical word unknown to the layman or the "dirty" one which he knows but is not supposed to utter in polite society. Those of you who may have read Casanova's *Memoirs* will remember that he once had an experience with a girl who, under sexual excitement, passed great quantities of gas. Being somewhat of an anthropologist, he wrote the case up. It is interesting that primitive man noticed the influence of emotions in producing borborygmus and flatulence. When I was a boy in Hawaii, the natives spoke of what we would call a big hearted man as "big bellied." The Australian savages have no word for sorrow except "bowels moving." When we turn to the King James version of the Bible we find the word bowels used where, in the revised version, the word heart is used.

SUBACUTE BACTERIAL ENDOCARDITIS

RECOVERY FOLLOWING INTRAVENOUS
SODIUM SULFADIAZINE

GEORGE F. DICK, M.D.
CHICAGO

Although there have been a few reports of favorable results from the use of sulfonamides in endocarditis, my own experience with them has been discouraging.

While there have generally been some improvement in fever following the use of sulfanilamide, sulfathiazole and sulfadiazine and some decrease in the number of colonies in agar plate blood cultures, we have obtained no extended periods of negative blood cultures in a fairly large experience.

In many instances the improvement obtained at first was not maintained, suggesting that perhaps the streptococci over a period of weeks or months became resistant to the action of the drugs employed.

I have had no better results in endocarditis with sulfadiazine administered orally and given up to the limit of tolerance than with preceding sulfonamides, but it has seemed to me less toxic. It was, therefore, thought justifiable to try massive dosage of sodium sulfadiazine¹ intravenously with the hope that all the streptococci might be killed before any resistance to the drug was established.

Although the necessary danger of massive dosage is apparent, the fact that I have in a rather large experience had such discouraging results from treatment seemed to justify such a trial.

REPORT OF CASE

A. H., a man aged 30, came to the outpatient department at Billings Hospital on April 20, 1942 complaining of weakness, loss of 22 pounds (10 Kg.) in weight and the loss of appetite and nausea for a month and pain in the right shoulder for two days. One month previous to admission, the patient had an infection of the right hand after a piece of brass was driven into the hand. He was treated by the company physician

and given sulfanilamide in wet dressings for six days. The hand improved, but the patient's general condition seemed to be worse. Sulfanilamide treatment was discontinued, and at that time the patient had a temperature of 100.4 F. He had since taken his temperature twice a day and had noted a variation from 98.4 to 102 F. The patient had not worked. On the Friday previous to admission he had severe chills. He also noted swelling of the ankles on one day the week before admission. Since the day before admission he noticed a sharp pain in the region of the right scapula. When he was first seen the blood pressure was 128 systolic and 75 diastolic and the temperature 100.2 F.

He was admitted to the medical service at Billings Hospital on April 21 for diagnosis. At that time there was noted a presystolic and a systolic murmur over the mitral area. Roentgenograms of the chest showed a moderately enlarged heart with the lung fields clear. The blood count showed 10,500 white cells and 4,580,000 red cells, there was 13.5 Gm of hemoglobin per hundred cubic centimeters. The urine showed a trace of albumin, an occasional red cell and also an occasional leukocyte.

A blood culture made on entrance showed an average of 51 colonies of *Streptococcus viridans* in each of the blood plates. Cultures in broth showed typical colonies of gram-positive streptococci forming long chains. Two days later a second blood culture showed an average of 41 colonies to the plate. On this day the patient was given 40 Gm of sodium sulfadiazine intravenously in 500 cc of water. About two hours after this injection the patient had some cramping abdominal pains, and half an hour later he vomited.

Whereas the urinary volume for the twenty-four hours preceding the injection was 1,065 cc, on the following day the urinary volume was only 215 cc and the urine contained some gross blood. On the second day after the injection the total twenty-four hour volume of urine was 15 cc, and the daily volume continued as follows: April 26, 50 cc; April 27, 25 cc; April 28, 130 cc; April 29, 375 cc; April 30, 947 cc; May 1, 1,400 cc. After this it continued normally.

Owing to the loss of fluid by emesis, the patient was given intravenous injections of 5 per cent dextrose in saline solutions to keep up his body fluids and electrolytes and on April 27 he was also given sodium lactate intravenously to maintain a normal pH. The blood levels of sulfadiazine and urea nitrogen during this period are shown in the accompanying table.

Levels of Sulfadiazine and Urea Nitrogen in the Blood

Date	Sulfadiazine		Blood Urea Nitrogen
	Free	Total	
4/23	89.0	90.0	
4/24	73.1	81.0	17.9
4/25	56.7	65.9	
4/26	45.9	70.9	35.9
4/27	37.4	66.9	44.6
4/28	32.8	60.1	44.8
4/29	28.0	56.5	73.1
4/30	23.7	47.7	86.2
5/1	15.6	39.5	93.7
5/3	3.1	9.0	71.4
5/5	0.5	1.1	49.3
5/11	11.9	13.0	7.3
5/13	12.2	13.0	4.9
5/15	12.4	13.2	6.4
5/17	39.9		
5/18	20.2		6.9
5/19	9.1	9.3	6.5
5/20	3.1	3.2	

A blood culture made April 26, three days after the intravenous injection of sodium sulfadiazine, was sterile, as were all subsequent blood cultures, made on May 1, 17 and 26.

The temperature following the injection of sodium sulfadiazine, which had previously varied between 98.6 and 100.4 F, fell to normal within a few hours, remained normal for five days and during the next six days varied from a maximum of 100.4 to a minimum of 98 F. After this period the temperature again returned to normal and has remained normal during the past month. On May 20 a slight diastolic murmur over the aortic valve was heard.

From the Frank Billings Clinic of the Department of Medicine, University of Chicago.

¹ This drug was furnished by Lederle Laboratories Inc., Pearl River, N. Y.

By May 5 the total sulfadiazine level in the blood had fallen to 11 mg per hundred cubic centimeters. The blood urea nitrogen was normal on May 8, and the patient had a normal temperature and normal urine and felt well. Although the blood stream was sterile it was decided to give more sodium sulfadiazine in order to insure, if possible, sterilization of the cardiac valves. Accordingly, beginning with 5 Gm, intravenous injections were given as follows: May 8, 5 Gm, May 11, 8 Gm, May 15, 10 Gm, May 17, 14 Gm. This was followed by a total sulfadiazine blood level on May 17 of 399 mg. Since this date the patient has received no medication except for a hematinic elixir and a daily dose of digiland 0.00033 Gm.

Six weeks after the drug was given, at the time of writing, the patient feels perfectly well and has had a normal temperature for a month. The sterility of the blood stream as indicated by blood cultures made during the past month probably indicates that his heart valves are free from living organisms and will remain so unless reinfection occurs.

SUMMARY

In a case of subacute bacterial endocarditis recovery from active bacterial infection followed the intravenous injection of 40 Gm of sodium sulfadiazine. Somewhat alarming but transient renal damage occurred. There was no evidence of permanent injury to the kidneys.

Clinical Notes, Suggestions and New Instruments

PENTOSURIA AND DIABETES MELLITUS

ROBERT E. MOSS, M.D. AND BURNHAM S. WALKER, M.D.
BOSTON

Although recognized¹ in 1892, few cases of chronic essential pentosuria have been reported. Enklewitz and Lasker² in 1933 were able to find reports of 100 cases, to which they added 12. They pointed out, however, that the condition is not excessively rare if consistently looked for in all instances in which a small amount of reducing substances is found in the urine. Marble³ reported in 1932 that 3 cases had been found at the Joslin Clinic in a series of 9,000 cases of mellituria and by 1940 was able to report recognition of 9 cases. He emphasized the likelihood of their being mistakenly classified as examples of renal glycosuria unless the type of urinary sugar is determined. Obviously there is equal danger of their being mistaken for cases of diabetes mellitus and of being treated as such.

The occurrence of chronic pentosuria in association with diabetes mellitus is definitely much less common than its occurrence as an isolated phenomenon. Enklewitz and Lasker² were unable to find a single example of the two conditions in one individual, and at the Joslin Clinic³ only 1 case was noted in which the diagnosis of diabetes mellitus might be justified. All students of the subject agree that pentosuria is found almost exclusively among Jews and predominantly in males. Because the patient who is the subject of the present report is of non-Jewish stock, is female and has undoubtedly diabetes mellitus along with pentosuria, her condition merits recording as an excessively rare medical curiosity.

From the Evans Memorial, Massachusetts Memorial Hospitals and the Departments of Medicine and Biochemistry, Boston University School of Medicine.

REPORT OF CASE

O. H., a white woman aged 25, married, was admitted to the Evans Memorial, Massachusetts Memorial Hospitals on April 28, 1942 for control of her diabetes.

The family history was negative for diabetes mellitus, and the past history was not significant, except for diabetes mellitus.

In April 1928, at the age of 11, she was first admitted to a neighboring hospital, where a diagnosis of diabetes was

Summary of blood and urine sugar reports and insulin dosage

made. She was found to have a fasting blood sugar of 520 mg per hundred cubic centimeters and urinary sugar of 11.2 per cent. Regulation was achieved with 20 units of regular insulin before the morning and evening meals. In 1930 she was readmitted because of diabetic coma from which she rapidly recovered with very little additional insulin. Under careful supervision she progressed normally in school, taking 40 units of regular insulin daily.

In 1938, because of anorexia, she was readmitted to the hospital. Vomiting began in the hospital and acidosis became severe with the carbon dioxide combining power of the plasma falling to 16 volumes per cent on the third day, despite hypoglycemic blood sugar levels. At this time she was shifted to protamine zinc insulin and was satisfactorily controlled by 36 units plus 16 units of regular insulin daily. Thereafter she was in fair health until the fall of 1940, when she developed the first of a series of attacks of right flank pain, fever and vomiting, associated with pus in the urine. A diagnosis of pyelitis was made, and an investigation by means of both intravenous and retrograde pyelography revealed no significant changes in the kidneys. There was persistent vomiting during February and March 1942, but blood sugar levels remained

Urinary Excretion of Dextrose and Pentose in Twenty-Four Hours

	Dextrose Gm per 24 Hrs	Pentose Gm per 24 Hrs
May 14	0.15	1.97
15	0.71	0.88
16	0.61	0.75
17	0.60	1.7
18	1.62	1.45
19	0.79	0.66
20	2.04	2.38
21	2.70	1.12
22	2.96	1.0
23	1.45	0.79
24	1.99	1

generally normal there was no acidosis and it was possible to reduce her insulin gradually to 24 units of protamine zinc insulin daily. It was noted that despite normal blood sugar levels, she frequently spilled appreciable amounts of sugar in the urine, although on several occasions the urine was free of reducing substances.

Four weeks before admission to this hospital the patient returned to her home and remained well until five days before admission at which time she had an insulin reaction. Two subsequent reactions occurred in rapid succession. In each she became unconscious and was restored to normal balance with difficulty. A puzzling feature of these episodes was the

finding of reducing substances in the urine concomitantly with the manifestations of hypoglycemia

Physical examination showed that she was small and thin. She weighed 89 pounds (40 Kg) on admission and stated that she had lost 25 pounds (11 Kg) in the past six months. The pupils responded normally to light and in accommodation. The heart was not abnormal. The lungs were clear and resonant throughout. The abdomen was normal. The blood pressure was 130 mm of mercury systolic and 70 diastolic.

The pertinent laboratory data are summarized in the chart and the table.

COMMENT

Several tests are available to indicate the nature of the reducing substance found in urine. A pentose does not ferment in the presence of yeast, it gives a specific reaction with Bial's reagent, and if it is D-xyloketose, it reduces both qualitative and quantitative Benedict's solution at room temperature in the course of several hours.² It is possible also to prepare an osazone, which has a specific melting point and to use polariscopic examination if further exact proof of the type of sugar is desired.

In our case the fermentation test was positive because of the dextrose present, and an osazone was not prepared because of the difficulty of separating the glucosazone from the xylosazone. Reliance was placed routinely on the Bial test and the room temperature reduction test. Many examinations by these methods showed pentose to be almost invariably present. In addition as shown in the table quantitative determinations of total urinary sugar by the method of Sumner⁴ and of total pentose by the method of Youngburg⁵ were carried out on eleven twenty-four hour urine collections. Although there is an appreciable variation in the amount of pentose excreted daily, there is a greater tendency toward a constant output than is discernible in the dextrose output. It is of interest that Enklewitz and Lasker⁶ noted a fairly direct relation between body weight and pentose excretion. They showed as well that drugs which are excreted as glycuronates will increase pentose excretion whereas rest, exercise, thyroid or modification of the carbohydrate or protein content of the diet has no influence on pentose excretion. Because ingestion of large amounts of fruit, particularly plums, cherries, grapes and prunes, rather frequently results in 'alimentary pentosuria,'¹ we fed our patient these fruits in abundance, beginning May 22. The results in the table show no significant increase in pentosuria.

The presence of a second sugar in the urine of this patient complicated the management of her diabetes. The history revealed that she had frequently presented the puzzling combination of hypoglycemic symptoms—even to the point of unconsciousness—along with a reducing sugar in the urine. Indeed, it was this clue that led to the suspicion that she might have pentosuria. Under such circumstances it becomes unreliable to attempt to regulate her insulin dosage according to her urinary sugar. Fortunately, she has an unusually keen perception of her own sensations and has been able to correlate these with her blood sugar levels to a remarkable extent. It is hoped that strict adherence to her diet, an occasional fasting blood sugar and attention to minor changes in general feeling will suffice to maintain her diabetes in a satisfactory state of control. As far as the pentosuria is concerned no treatment is necessary or known. All the evidence indicates that chronic essential pentosuria has no detectable influence on health.

SUMMARY

A case of chronic essential pentosuria, occurring in association with diabetes mellitus, was observed. This combination of abnormalities is very rare, and extremely so in a non-Jewish female.

Three simple tests are available for the differentiation of pentose in the urine. Recognition of pentose, when present, is important as it may significantly complicate the management of diabetes.

A METAL SAFETY AND GLARE GOGGLE

EDWARD STIEREN, M.D., PITTSBURGH

A safety goggle for industrial use has been designed which has the advantage over glass protective goggles in that it cannot be broken by flying particles, and vision is not interfered with by steam perspiration or grease.

It consists of two aluminum shields fitted into soft rubber with an adjustable band of the same material to hold them in place.

In the center of the shield is a horizontal opening 1 mm in width and 40 mm long. A vertical opening of the same width and 10 mm long bisects the horizontal opening 10 mm from the nasal end. In addition a 20 mm long opening is added at an axis 15 degrees off horizontal for vision in the lower field.

Metal safety and glare goggle

As its crude prototype was originated by Eskimos to prevent snow blindness, the arrangement of the slots in this goggle by admitting a minimum of light reduces glare, and the goggle can be worn comfortably in bright light.

The goggle was designed by Anthony Flocker, M.E., and is marketed by the Kerlo Corporation, 521 Fifth Avenue, New York.

Union Trust Building

TROMBIDIOSIS (CHINGER BITFS)

RELIEF OF ITCHING WITH ETHYL AMINOBENZOATE IN FLEXIBLE COLLODION

RICHARD I. SUTTON, JR., M.D., KANSAS CITY, MO.

Use of the following prescription designed at the insistent demand of a frantic colleague, Dr. Wade Miller, provided him with the best relief of any chigger bite antipruritic he ever tried, and he has tested many.

	Cm. or Cc.	gr. xxx
R. Ethyl aminobenzoate	2	
Flexible collodion	15	3ss
Put in bottle with rod in stopper		
Sig. Paint itching bite as required for relief of itching		
Keep away from flame		
Keep tightly stoppered		

Application of this clear, colorless, camphoraceous, locally anesthetizing, nonirritant, adhesive, inconspicuous medicine stops sensation for from four to eight hours, enabling the sufferer to sleep at night and to live in comparative comfort through the period required for healing. It has given satisfaction to several patients of mine. I should expect it to be as useful for any other kind of bite. I should hesitate to use it on large areas of skin. If a hemolytic *Staphylococcus aureus* happens to be imprisoned beneath the collodion, as I have observed, a small bleb tense with seropurulent fluid, quickly develops. This may

The safety goggle was demonstrated by Dr. Stieren before the Section on Ophthalmology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1942.

be drained and wiped with 2 per cent aqueous solution of methylosaniline, which is promptly curative

As a repellent, I know of nothing superior to Sta-Way, made by National Carbon Company, Inc., New York. I do not know its ingredients. It has not irritated the skin of any patient I have seen

LABORATORY INFECTION WITH THE VIRUS OF LYMPHOCYTIC CHORIOMENINGITIS

A TWO YEAR STUDY OF ANTIBODY RESPONSE

ALBERT MILZER PH.D. AND SIDNEY O. LEVINSON M.D.,
CHICAGO

Although many investigators have been actively engaged in experimental work with the virus of lymphocytic choriomeningitis or with infected animals, comparatively few have contracted the disease or, of those tested, few have developed neutralizing antibodies in their serum.¹ Lepine and Sautter² were first to report a laboratory infection of lymphocytic choriomeningitis. Virus was isolated from their patient's blood and urine, and complement fixing antibodies were demonstrated in the patient's serum during convalescence. The serums of 2 persons who had worked for two years with the same virus strain and infected animals failed to fix complement. Lepine and Sautter mention no attempt to detect virus neutralizing substances in their patient's serum. They believe that their patient became infected nine days before onset of symptoms by fragments of contaminated glass that were accidentally splattered into her eye during the process of grinding infected guinea pig tissues with powdered glass. More recently, Armstrong and Hornbrook³ have described a case without central nervous system manifestations in a laboratory worker engaged in choriomeningitis research at the National Institute of Health, but the manner of infection is not discussed. The virus was isolated from the blood, and the patient developed a high titer of specific neutralizing antibodies six weeks after the attack. Armstrong⁴ also states that "a number of cases of choriomeningitis have developed among laboratory personnel handling infected mice." He, however, does not elaborate on details of the degree of contact or manner of infection.

The usual experience of noninfectivity by exposure to the virus and infected animals among laboratory workers is also borne out in animal experimentation. Various workers⁵ have noted that normal mice and guinea pigs are not readily infected by contact with artificially infected animals. Traub⁶ and Haas,⁷ however, have shown that white mice transmit infection to their offspring in utero and in infancy and that naturally infected mice transmit infection by contact more readily than artificially infected animals.

Because the natural mode of transmission of lymphocytic choriomeningitis in either man or infected animals is unknown, we feel that it is important to record the following case of

laboratory infection in one of us (A. M.), in which there is evidence that infection came from contact with infected monkey lice. This is discussed in detail. The virus of lymphocytic choriomeningitis was isolated from the spinal fluid during the acute stage, and both neutralizing and complement fixing antibodies against the isolated and two known strains of virus were detected in the serum during subsequent recovery. Blood specimens were obtained at frequent intervals during and following convalescence and as long as twenty-six months after the attack in order to determine the time of appearance and respective titers of complement fixing and neutralizing antibodies in his serum.

REPORT OF CASE

A. M., a white man aged 23, admitted to the hospital on Aug. 2, 1939, complained of severe frontal headache for two days. Twelve days previously the patient had a severe upper respiratory infection, which gradually improved, although it had not completely cleared up with the onset of the present illness. The day before admission he had chills, sensations, profuse sweating, generalized weakness, and pain in the back and in the back of the neck. There had been constipation for two days.

The patient was well nourished, quite prostrated and rather lethargic. His temperature was 103.4 F rectally, pulse rate 100 and respiratory rate 22 per minute. His face was flushed, and he was covered with profuse sweat. The general physical examination was otherwise completely negative. There was definite neck resistance to anterior flexion and decided back resistance, so that the patient could not bend over. Muscle power in all extremities was good, and reflexes were equal and active. No pathologic signs were present.

For the next two days the temperature ranged between 102 and 105 F. The headache continued very severe, and the patient complained, in addition, of pain behind the eyeballs. In the afternoon of August 3 a lumbar puncture was performed, which yielded 10 cc of clear spinal fluid under normal pressure. Examination of the spinal fluid revealed 8 lymphocytes per cubic millimeter, a total protein content of 51 mg per hundred cubic centimeters and a sugar content of 67 mg. On August 4 his leukocyte count was 4,350 per cubic millimeter, of which 73 per cent were polymorphonuclear leukocytes with a shift to the left, 21 per cent lymphocytes and 6 per cent monocytes. In addition to the leukopenia, the throat was reddened and several small grayish ulcers were noted in the left tonsillar fossa.

The patient continued acutely ill for the next several days with headache, myasthenia and loss of weight. The temperature continued to range from 101 to 104 F. Repeated blood cultures showed no growth. The white blood count rose to 7,850 per cubic millimeter on August 5 and remained between 5,000 and 8,000 until August 10, after which it varied between 12,000 and 16,000. Stool cultures were negative for intestinal pathogens, but on August 11 and August 12 *Endameba histolytica* trophozoites and cysts were observed. Agglutination tests of serum specimens taken on August 7 and August 17 for typhoid, paratyphoid A and B, tularemia, *Brucella abortus*, *Brucella melitensis*, *Bacterium shigae*, *Bacterium sonnei* and *Bacterium paratyphosum* (Flexner and Hiss) were negative, as were the Weil-Felix reaction and heterophil agglutination. The Wassermann and Kahn reactions of the blood were negative. A roentgenogram of the chest was normal.

The temperature dropped to about 100 F on August 9, and a low grade fever persisted for the next week. On August 14 emetine therapy was started, the patient was given 1/2 grain (0.03 Gm) of emetine hydrochloride on the first two days and then a grain (0.06 Gm) daily subcutaneously for the next six days. Carbarsone was then administered. The patient's temperature became normal on August 16 and remained normal until he was discharged on August 22. During hospitalization the patient lost 17 pounds (7.7 kg) and he did not completely regain his weight and strength until three months after discharge. No residual after-effects from this illness have been noted.

From the Samuel Deutsch Serum Center, Michael Reese Hospital.

EXPERIMENTAL RESULTS

In previous publications⁸ our stock guinea pigs and white mice were shown to be free from latent choriomeningitis infection by repeated intracerebral inoculations with sterile corn starch (Kingsford's), broth, normal brain suspensions and 52 spinal fluid specimens from various human central nervous system infections. Furthermore, we have not encountered any stock animals that were immune to inoculation with known virus. Rectal thermometers which were used to take guinea pig temperatures were disinfected in solution of formaldehyde U S P diluted 1 to 10 to eliminate the possibility of intrarectal transmission of the virus reported by Shaughnessy and Zichis.⁹ No ectoparasites were noted on stock guinea pigs and mice, and all animals were housed in new quarters free from infestation with bedbugs, cockroaches, house mice and domestic rats, so that the possibility of infection arising from these sources was minimized.

Two cubic centimeters of cerebrospinal fluid taken from the patient on Aug. 3, 1939, was inoculated subcutaneously into a guinea pig weighing 440 Gm. Five-tenths cubic centimeter seeded into suitable aerobic and anaerobic culture mediums and incubated at 37 C showed no growth in fourteen days. The inoculated guinea pig had a temperature of 105.8 F three days after inoculation and died in twelve days. This animal lost approximately 30 per cent of its initial body weight. At necropsy, the brain was macroscopically hyperemic, and areas of interstitial bronchopneumonia were seen in stained lung

Titer of lymphocytic choriomeningitis neutralizing and complement fixing antibodies in patient's serum at various intervals during convalescence and after recovery

sections. No bacteria were isolated from the brain tissues and heart blood cultured in aerobic and anaerobic mediums.

The brain was removed aseptically, and a 10 per cent suspension by weight was prepared in buffered saline solution. Five-tenths cubic centimeter was injected subcutaneously into a second guinea pig, weighing 430 Gm, and 0.03 cc intracerebrally into each of 4 white mice. On the seventh day all inoculated mice had ruffled coats and severe body tremors. The mice all died the next day with characteristic signs of experimental lymphocytic choriomeningitis.¹⁰ In each instance no bacteria were isolated from the brain tissues and heart blood. The second passage guinea pig had pyrexia (104.4 F) two days after inoculation and died seven days later. It also lost approximately 30 per cent of its initial body weight. Its brain was grossly hyperemic, and an interstitial bronchopneumonia was noted in stained lung sections. The brain tissues and heart blood were bacterially sterile.

The virus was then transferred to a third passage guinea pig, which was killed while moribund in order to identify virus present in its brain tissues by means of a specific serum neutralization test. The technic of this test is described in a previous publication.¹¹ The recovered virus was shown to be that of lymphocytic choriomeningitis because guinea pigs inoculated with mixtures of undiluted monkey lymphocytic

choriomeningitis antiserum¹² and serial tenfold virus dilutions ranging from 10^{-1} to 10^{-1} were completely protected, while control guinea pigs inoculated with mixtures of normal monkey serum and the same virus dilutions succumbed in nine to fifteen days with typical signs of choriomeningitis.¹⁰ At the time of the neutralization test the virus titer was 10^{-4} .

The new strain was maintained by subcutaneous inoculation in guinea pigs. It was found by titration experiments that it had reached its maximum pathogenicity after the tenth passage, so that it would consistently kill guinea pigs when 0.5 cc of a 10^{-4} dilution in buffered saline solution was inoculated subcutaneously. To date the virus has been passed for 106 generations and is as virulent for guinea pigs and white mice as the W E (Rivers) and J P strains.¹¹

Other studies show that there is a complete cross immunity between the isolated (A M) strain, the W E (Rivers), the J P strain and the Coggeshall strains¹³ as demonstrated by resistance to challenge inoculations in white mice which had been infected and had recovered. The new strain suspended in nutrient broth of pH 7.2 (5 per cent brain tissue suspension) and centrifuged at 2,000 revolutions per minute for ten minutes to remove large tissue particles readily passes through previously tested Berkefeld N and W candles at a negative pressure of 31 cm of mercury. It has also been successfully cultivated for ten passages on the choriollantoic membrane of the developing chick embryo apparently without loss of virulence. Other studies on cultivation of the virus in the developing chick embryo are now in progress and will be reported later. Microscopic examinations of brains of guinea pigs and white mice that succumbed to the new strain revealed round cell infiltration of the meninges and choroid plexus identical or very similar to that produced by the W E,¹⁰ J P and Coggeshall strains of virus.¹⁴

Specimens of serum obtained from the patient three weeks after the onset of illness, at frequent intervals during convalescence and after complete recovery had occurred were titrated for both neutralizing and complement fixing antibodies against the virus. The results are shown in the accompanying chart. As previously stated the new strain had reached its maximum virulence after the tenth guinea pig passage and has been continuously passaged since isolation without alteration. Thus all serum specimens after the first have been titrated against a stabilized virus. The neutralization tests were performed by inoculating guinea pigs subcutaneously with mixtures of equal parts of undiluted serum and serial tenfold virus dilutions according to the technic already described.¹¹ Each specimen of serum was titrated for neutralizing antibodies at least twice and in some instances as much as six times in connection with other studies.¹⁴ In the majority of instances the same titer was obtained in duplicate tests. The complement fixation test was performed with an antigen consisting of saline extracts of pooled infected guinea pig spleens using essentially the same technic described by Smadel, Baird and Wall.¹⁵ In order to eliminate false positive reactions,¹⁶ the antigen was stored several weeks at 5 C before use. Known negative and positive control serums were included in all titration experiments.

It is interesting to note that complement fixing antibodies were present three weeks after the onset of symptoms and persisted at the same level for twenty-six months after recovery, as shown on the chart. On the other hand, neutralizing antibodies were not detected three weeks after onset of symptoms but appeared after eight weeks, reaching a maximum titer in five and a half months and then declining so that a constant level was reached eleven months after onset of symptoms. These results parallel those of Smadel and his associates¹⁵ who

reported that complement fixing antibodies were detected in guinea pigs two weeks after inoculation, while neutralizing antibodies were not demonstrable before the fourth to the sixth week. Our results differ from those of Smadel, however, in that the titer of complement fixing antibodies was the same twenty six months after the attack, while Smadel noted a decline in titer after the peak was reached six weeks after onset of the disease. Moreover, he found that serums taken from patients six to eight weeks after onset of the disease fixed complement and neutralized the virus, while serum drawn one and one-half to three years after the disease in the same patients still neutralized the virus in all but 1 instance, but none definitely fixed complement.

The immune serum was also found to possess neutralizing and complement fixing antibodies in the same titer against the J P strain as for the new strain of virus six months after onset of symptoms and on numerous occasions since then. It also neutralized the W E (Rivers) and the Coggeshall strains of choriomeningitis virus. Serum collected twenty-six months after the attack failed to neutralize the D 219 strain of the St Louis type of encephalitis virus¹⁷ and the B A I strain of the western type of equine encephalomyelitis virus¹⁸ in neutralization tests performed according to the technic described by Howitt¹⁹.

SOURCE OF INFECTION

About six days before onset of illness the patient was engaged in an experiment attempting to transmit the virus of lymphocytic choriomeningitis from monkey to monkey by means of the rhesus monkey louse, *Eupedicinus longiceps* (Paget²⁰). During the experiment the patient noted several lice on his hand, which had come from handling a monkey dying from experimental lymphocytic choriomeningitis. Other lice which were recovered from the infected monkey on the same day were ground in saline solution and injected subcutaneously into a guinea pig, and the animal succumbed with typical signs of lymphocytic choriomeningitis in ten days. Dr H E Ewing,²¹ of the United States Bureau of Entomology and Plant Quarantine, states that monkey lice are known to bite man.

Although the patient is not certain that the lice bit him, circumstantial evidence would seem to indicate that they were the source of his infection. It is possible of course that infection may have resulted from skin contamination with infected louse excreta or with infected crushed lice, since Shaughnessy and Zichis⁹ have shown that the virus can penetrate the normal, unscarified skin of guinea pigs. The patient had worked with the virus in the laboratory for almost two and one half years and was always careful to observe the usual precautions taken in handling infectious agents. About one year previously some infected guinea pig brain tissue had accidentally splattered into his eye without resulting illness or development of specific neutralizing antibodies. Immediately after the accident his eye was rinsed several times with a weak aqueous solution of boric acid. Fortunately, at the time of the accident the infectious material was free from sand or other abrasives. In this respect our case differs from that reported by Lepine and Sautter, in which infection resulted from contaminated fragments of glass that flew into their patient's conjunctiva. Lepine and Sautter had failed to prevent infection by instilling 2 per cent solution of mild protein silver into their patient's eye immediately after the accident. It is interesting to note that the incubation period before onset of symptoms was nine days in the case of Lepine and Sautter while it was six days in ours. The similarity of incubation is additional evidence that our patient may have been infected by the monkey lice.

Later experiments which were carried out prove that the virus survives for at least twenty-four hours after infected lice

are removed from their host and kept at room temperature (22 to 25 C.)¹⁴ One attempt to transmit infection from an infected to a normal rhesus monkey by uncontrolled feeding of the monkey lice failed. Armstrong⁴ however, has recently announced successful transmission of infection in 2 of several trials by transferring approximately 100 lice taken from an infected monkey to a normal one.

COMMENT

There are a number of aspects of this case which are interesting. First, it should be pointed out that, although the patient had clinical meningeal irritation the spinal fluid showed no increase of cells and that therefore the usual routine examination of the spinal fluid would have resulted in completely missing the diagnosis. A normal spinal fluid during the early acute stage of lymphocytic choriomeningitis has to our knowledge not been previously reported although Howard²² recorded 1 case in which it was normal nine days after onset. The symptomatology actually indicates a disturbance of an encephalitic character. Furthermore, the disease was far from "benign." This adjective has been dropped in recent discussion, but it should be stressed that this illness may be quite severe because it may be accompanied by paresis or paralysis. We have observed such occurrence in our own experience, and it has been described by others.²³ Further evidence that the disease is not necessarily a mild one is borne out by the reports of fatal cases in which virus was isolated.²⁴

A very interesting sidelight during the observation of this case was leukopenia. The white blood cell count was so low that, although there was no granulopenia, pentnucleotide was administered. This was done because in addition to the leukopenia we observed small pharyngeal ulcers.

The finding of cysts and trophozoites of *Endameba histolytica* led us to believe that this was a very atypical case of amebic dysentery. As the case ultimately turned out, we realized that this was an incidental finding in a condition which had probably existed for an indefinite time in an unrecognized form. The therapy cleared this infection completely.

As has been reported by Scott and Rivers,²⁴ virus neutralizing antibodies are not detected in serum taken during the acute stage. However, as shown in the chart, virus neutralizing substances did appear during convalescence and rose to a certain level, which has been maintained for more than two years. This is additional confirmation of the fact that the patient had an attack of lymphocytic choriomeningitis and also is significant in indicating the duration of persistence of the virus neutralizing substances in the blood stream.

Although there is no direct proof that lymphocytic choriomeningitis is insect borne, there is evidence that this disease can be transmitted by certain arthropods in laboratory experiments. Thus, Shaughnessy and Milzer⁵ reported experimental infection of all stages of the life cycle of the Rocky Mountain wood tick (*Dermacentor andersoni*). Coggeshall¹³ was able to transmit the virus from guinea pig to guinea pig by the bites of infected *Aedes aegypti* mosquitoes. The senior author has confirmed Coggeshall's work¹⁴ and has also shown that bedbugs and a species of blood sucking mite (*Atricholaelaps glasgowi*) can transmit lymphocytic choriomeningitis experimentally. As mentioned before, we have shown that the virus can survive for at least twenty-four hours in infected rhesus monkey lice (*Eupedicinus longiceps*) but we were unable to transmit infection in a single uncontrolled feeding experiment, while Armstrong succeeded in transmitting infection in two of several trials. Findlay, Stuart-Harris and MacCallum¹ showed in a recent publication that the lymphocytic choriomeningitis

virus was retained "for at least some hours" in human body lice (*Pediculus humanus var corporis*) that were allowed to feed on an infected monkey. Other arguments suggesting that lymphocytic choriomeningitis might be an arthropod borne disease in nature are summarized in a previous publication¹⁴. In view of the recent evidence that gray mice (*Mus musculus*)²⁶ and dogs²⁷ may possibly be a reservoir of this disease from which man may become infected, further work along these lines of epidemiology and transmission might further elucidate this problem.

SUMMARY

In a case of laboratory infection of lymphocytic choriomeningitis, virus was isolated from the apparently normal spinal fluid during the acute stage and the patient subsequently developed a high concentration of both complement fixing and virus neutralizing antibodies, the titer of which was studied over a period of twenty-six months. The infection may have come from contact with infected rhesus monkey lice.

Special Clinical Article

PROGRESS IN THE ARMY'S FIGHT AGAINST MALARIA

CLINICAL LECTURE AT ATLANTIC CITY SESSION

JAMES STEVENS SIMMONS, M.D.,
PH.D., Sc.D., D.P.H.

Colonel M. C. U. S. Army, Chief Preventive Medicine Service,
Office of the Surgeon General, U. S. Army

WASHINGTON, D. C.

The entry of the United States into the present war and the dispatch of American troops to fight in new tropical regions all over the world has restored malaria to its former position as one of the Army's most important disease hazards. Malaria has always threatened our armed forces, and throughout the century and a half of our national existence the medical department of the Army has been engaged in a continuous fight against this ancient military scourge. Prior to 1900 the malarial fevers were one of the most serious causes of disability and death, during both war and peace, and little or no progress was made in their prevention until the beginning of the present century. Since that time, the rapid development of information concerning the mosquito transmission of malaria has afforded control methods which have been applied successfully, especially among troops living in permanent garrisons in the continental United States. This has caused a spectacular decrease in the malaria admission rates for the total army, and during recent years most of the infections have occurred among men living under field conditions in endemic regions.

The latter fact has a significant bearing on the importance of malaria during the present military emergency. The difficulties encountered in the control of malaria in the field during peacetime are naturally increased under the infinitely more trying conditions of war. Moreover, a much larger proportion of the troops will be exposed to malaria because of the extensive tropical areas to be occupied. Thus the medical department and the entire

medical profession are faced with the vital problem of protecting American troops against malaria under all of the varied and difficult conditions to be encountered during this war.

In order to visualize the scope of the present problem, it is proposed (1) to review briefly the Army's past experience with malaria, (2) to indicate certain new malaria hazards created by the present military situation and (3) to mention some of the more important measures that have been adopted by the Army in order to develop an effective wartime malaria control program.

THE ARMY'S PAST EXPERIENCE WITH MALARIA

The United States Army has never been free from malaria. The disease was widely distributed in this country during the colonial period, and it has occurred among American soldiers during each of the one hundred and sixty-seven years that have passed since the battle of Lexington.

For convenience, the Army's experience with malaria may be divided into three periods, characterized respectively by the availability of specific information concerning (1) the treatment, (2) the etiology and (3) the transmission of the disease.

1 Period of Clinical Recognition (1776-1880)—During the first of these periods, from 1776 to 1880, there was no information as to the cause of malaria or of the manner of its transmission. However, the disease was recognized clinically, and cinchona bark and later quinine were available for treatment. Boyd,¹ quoting Blanton,² states "As early as 1776 the Continental Congress ordered the Medical Committee to forward 300 pounds of Peruvian bark to the Southern department for the use of the troops", also "Jackson," a British Army surgeon attached to one of the regiments of Lord Cornwallis's Army, made extensive use of Peruvian bark in treating the abundant intermittent fevers from which the British Army suffered in its Southern campaign." Quinine was isolated in 1820, and three years later it was prepared commercially in Philadelphia. Within a short time quinine replaced the bark in treatment, and before and during the Civil War it was used as a prophylactic.

The malaria rates for the Army from 1776 to 1818 are not available, but the disease was a common cause of sickness, disability and death throughout that period. During the next sixty-one years the annual admission rates of white troops per thousand in the United States varied from lows of 200 to highs of around 1,000, as is shown in figure 1. In other words, from 20 to about 100 per cent of the troops were infected during these years. Indeed, malaria was more prevalent than typhoid, and often it was responsible for more than one fourth of the total disease admissions to army hospitals. The malaria mortality was also relatively high during this period. Prior to 1870 the mortality rates per thousand varied from lows of 0.22 to highs of 8, and during the next decade from lows of 0.23 to highs of 1.3.

Throughout this early period, malaria occurred in all sections of the United States, but it was most prevalent among troops located in the South. The disease was most common during periods of war, and in the latter years of the Civil War the infection was almost universal.

3 Jackson R. A Treatise on the Fevers of Jamaica with Some Observations on the Intermitting Fevers of America, London J. Murray, 1791

2 Period of Etiologic Knowledge (1880-1900) — Information as to the cause of malaria was available during the last two decades of the nineteenth century. As early as 1876 Joseph Jones identified malaria plasmodia in dried human blood⁴. Army surgeon Lavarani demonstrated the organism in the blood of a patient. Six years later, George M. Sternberg, who subsequently became the Surgeon General of the Army, demonstrated malaria parasites to Dr. William H. Welch in the latter's laboratory in Baltimore¹. However, this knowledge spread slowly, and specific diagnostic methods were not generally used until much later.

The Army's annual admission rates for malaria declined from 200 per thousand in 1880 to a level of about one half that figure during the period 1887-1897. A similar decrease in mortality occurred. In 1880 the annual death rate per thousand was 0.56, and from 1889 to 1898 it was less than 0.2. This reduction in malaria was influenced by many factors including the agricultural development and civic improvement in communities near Army garrisons. However, in many posts the rates remained extremely high, and a large percentage of the troops were infected each year.

When the Spanish-American War began much of the pioneer experimental work on the mosquito transmission of malaria had been done, but the results were neither complete nor generally accepted. American troops were exposed to infection both in the United States and on the tropical frontiers established during the war, and the incidence of malaria increased abruptly.

In 1898 the admission rate for the total Army rose to 640 and the death rate to 2.3 per thousand. The disease was common in Cuba, and after the capture of Santiago about half of our forces there were disabled by malaria.

3 Period Since Discovery of Mosquito Transmission (1900-1942) — The third period, which began in 1900, just after the discovery of the mosquito transmission of malaria, has been characterized by great progress in the control of the disease in the Army. During the American occupation of Cuba subsequent to 1900 Gorgas and LePrince⁵ demonstrated the effectiveness of mosquito control. However, with a few exceptions anti-mosquito sanitation was not practiced extensively in the United States until more than a decade later. During the period 1904 to 1914 Gorgas and his associates carried on their monumental malaria control campaign in Panama and obtained results which convinced the world of the importance of attacking the mosquito vectors. About 1912

the U. S. Public Health Service started field studies of malaria in the southern part of the United States which later resulted in rather extensive mosquito control programs in various civilian areas.

The value of these control activities to the Army is clearly reflected in the rapid decline in the annual malaria infection rates during the present century. As shown in figure 2, the rate per thousand for all white troops in the Army, regardless of location, was over 700 in 1900. For the next three years the rates were 392, 254 and 183 respectively, and in 1916 the rate was 41. During World War I relatively few of our overseas forces were located in malarious regions, and the troops in this country were protected by an effective anti-mosquito campaign. In 1917, 1918 and 1919 the annual rates were 9.5, 2.7 and 1.9 respectively. Since that time they have varied from a high of 10.9 per thousand in 1921 to lows of 3.8 in 1938 and 1939. The annual death rates for the entire period from 1900 to date have been less than 0.1 per thousand. The influ-

Fig. 1—Malaria in the United States Army: annual admission and death rates per thousand white enlisted men in the continental United States (from U. S. Army Medical Museum negative 73243).

ence of geographic location is indicated in this chart by a comparison of the admission curves for white troops located in the continental United States, the Philippines and in Panama. The decided difference between the relatively high prevalence in Panama compared with that in the Philippines may be attributed to many factors including differences in the habits of the anopheline vectors of the two tropical regions⁶.

Thus it may be stated that under the conditions which have prevailed in the Army during the present century, the medical department has been highly successful in its campaign against malaria. By the vigorous application of all the control methods available, it has been possible to protect troops living in permanent garrisons both at home and abroad. A large proportion of the reported cases have occurred in endemic regions in the southern part of the United States and in our tropical possessions. The incidence of malaria among troops stationed in Panama has been much higher than in the

NEW MALARIA HAZARDS CREATED BY THE PRESENT WAR

In 1939 when war in Europe appeared imminent there was very little malaria in the United States Army. However, anticipating our involvement in the present world conflict, the Surgeon General began to revise the plans of the medical department to meet any situation that might arise. An important feature of these plans was the strengthening and modification of the Army's program for the control of malaria under the conditions peculiar to mobilization and war. The wisdom of this course was borne out by subsequent events, which rapidly elevated malaria from the status of a disease nuisance to the position of a dangerous hazard. These events were (1) the rapid mobilization of our defense Army and the concentration of troops for training in Southern areas in which malaria is endemic, (2) the development of fortifications in our tropical bases in the Caribbean and (3) the wide dissemination of American troops in the tropical regions of the world which followed our entry into the war.

THE WARTIME PROGRAM FOR THE CONTROL OF MALARIA

The scope of the Army's wartime program for the control of malaria may be visualized by a brief consideration of (1) certain general measures which augmented the program, (2) the results of an intensified anti-mosquito campaign inaugurated in all permanent camps during 1939 and (3) plans which have been made for the protection of combat forces in malarious regions abroad.

1 *General Measures*—Some of the general measures that are of importance in connection with the present program will be mentioned.

(a) *The Preventive Medicine Service*—The first of these measures was the establishment in the Office of the Surgeon General, during 1940, of a section now designated as the Preventive Medicine Service. This service includes a subdivision devoted entirely to the control of malaria and other tropical diseases, which is directed by an eminent malariologist with an extensive international experience in the practical control of the disease.

(b) *The Commission on Tropical Diseases, Army Board for the Control of Epidemics*—During the same year there was organized under the Preventive Medicine Service a group of civilian consultants to the Secretary of War known as "The Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the United States Army." This board, which is now composed of 110 consultants, includes nine special commissions one of which is the "Commission on Tropical Diseases." Its members are available at all times for emergency work in the field should they be required to combat epidemics of tropical diseases.

(c) *Subcommittee on Tropical Medicine, National Research Council*—The Surgeon General has also been assisted materially by the Subcommittee on Tropical Diseases, which was organized in 1940 at his request by the Division of Medical Sciences, National Research Council. This subcommittee has advised the Army on matters of policy and has helped in the preparation of circular letters on tropical diseases, in the planning of training programs and in the promotion of necessary research projects.

(d) *Other Health Agencies*—The Army has also obtained the close cooperation and assistance of various other health organizations. These include the Rockefeller Foundation, the American Red Cross, the federal and state health services and the United States Department of Agriculture. During 1940 the Army made arrangements whereby the United States Public Health Service supplements the anti-mosquito work done on military reservations by sanitating extramilitary civilian areas in the United States, Puerto Rico and Hawaii. More recently plans have been made for similar extra-

Fig. 4—Monthly malaria rates in the U. S. Army in the continental United States during 1941 as compared to 1917, 1918 and 1919 (total monthly admissions per annum, from U. S. Army Medical Museum negative 73214).

military work to be done in certain foreign areas of the Western Hemisphere by the Coordinator of Inter-American Affairs.

(e) *Laboratories, Personnel, Training, Supplies*—The program has also been strengthened by such general measures as (1) the expansion of all of the Army's diagnostic and sanitary laboratory services, (2) the pro-

urement of additional sanitary engineers, medical entomologists and malarialogists and their assignment to stations where the disease is endemic, (3) the training of medical personnel in the control of tropical diseases, (4) long range planning to insure adequate supplies of the drugs and other materials required for the prevention and treatment of malaria, and (5) the initiation of many research projects designed to afford better facilities for the control of malaria

2 Intensification of Anti-Mosquito Campaign in Permanent Camps—In 1940, careful plans were made to carry out an intensified anti-mosquito campaign in all permanent camps posts and stations in this country and abroad. When the mobilization of our present Army began it was realized that the rapid induction of large numbers of recruits and their assignment to newly constructed training camps, many of them located in the South, would increase enormously the opportunity for infection with malaria. Army sanitary engineers were assigned to the headquarters of corps areas and the larger camps, and the services of entomologists and malarialogists were made available. After completion of preliminary surveys, the mosquito eradication work was started early in the spring of 1941. The campaign was directed at *Anopheles* control, but some pest mosquito eradication was included. The work in this country was continued throughout the year in the 160 stations indicated in figure 3.

This campaign, in which all of the approved methods of mosquito control were used, was confined to the limits of military reservations, as the United States Public Health Service is responsible for extramilitary sanitation. The cost of the Army program, which was almost 2 million dollars, was amply justified by the relatively low incidence of malaria during this period.

In figure 4 the monthly malaria admission rates per annum for the Army in the continental United States during 1941 and 1942 are superimposed on the rates for corresponding months of 1917 and 1918.

In figure 5 the rates by months for 1941 are compared with the high, low and mean rates by months for the ten peacetime years from 1931 to 1940. The 1941 curve shows a peak in October, which was due to infections contracted by troops while away from their sanitized garrisons on maneuvers, but for the other months the infection rates were relatively low. In spite of the enormous increase in the size of the Army, the annual rate for 1941 was only 17 per thousand.

This effective campaign is being continued and a budget of 5 million dollars has been approved for the fiscal year 1943.

3 Modification of the Wartime Control Program to Protect Troops Abroad—The changing military situation during the last two years has afforded an increasing number of new tropical fronts at which American troops are exposed to malaria. The acquisition of the Caribbean bases from Great Britain early in 1941 expanded our tropical frontiers to include numerous outlying islands. Since the declaration of war last December,

our frontiers have been extended still further, and we now have troops located in most of the tropical and semitropical regions of the world. As malaria is the most widespread of all tropical diseases, and one of the most difficult to deal with effectively under wartime field conditions, it has been necessary to modify and further reinforce the Army's control program in order to meet this new situation. Some of the more important features of this altered program are indicated here.

(a) **The Collection of Data Concerning Malaria in Foreign Countries**—In 1940 the Surgeon General started an organization now a part of the Preventive Medicine Service and designated the Division of Medical Intelligence for the purpose of collecting specific information about the health facilities and disease hazards of every country in the world. These data are carefully analyzed and incorporated into individual reports, which are used as a basis for specific recommendations made by the Surgeon General for every military force leaving our shores.

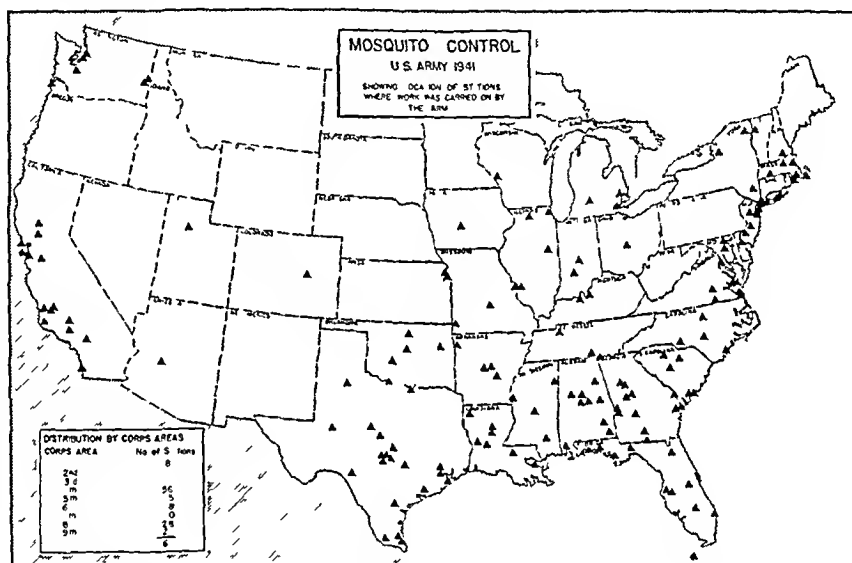

Fig. 3—Location of mosquito control stations in the continental United States (from U. S. Army Medical Museum negative 73215)

(b) **Malaria Control in the Caribbean Bases**—When our Caribbean bases were acquired from Great Britain, the Surgeon General organized a special health service to assist the Army engineers responsible for their construction. The officers of this service helped in the selection and sanitation of the construction sites and developed medical facilities for the protection of the health of the civilians engaged in the work. Malaria is one of the most important diseases in the Caribbean region, and the problem of its environmental control differs in the individual islands depending on various factors, especially the habits of the local anopheline mosquitoes. In Antigua for example, the main carriers of malaria are *Anopheles albimanus*, which breeds in fresh, sunlit still water, and *Anopheles tarsimaculatus*, which prefers brackish tidal swamps. In Trinidad, on the other hand, there are about ten other species, and the second most important vector is *Anopheles bellator*, which breeds in collections of water in a species of air plant a parasite of the Immortelle tree. Before the military base was constructed in Trinidad medical entomologists were sent there to investigate this mosquito. Within three months Dr. Lloyd Rozeboom of the Johns Hopkins School of Hygiene and Public Health had

incriminated *A. bellator* as an important carrier of malaria, thus indicating the necessity of eliminating its arboreal breeding places. The effectiveness of this Caribbean health service is indicated by the fact that the health of the personnel stationed at these bases has been excellent in spite of its unusual exposure to malaria and other tropical diseases.

(c) **Malaria Control Among Troops in the Field**
The control of malaria among troops under less permanent field conditions, on many of our other tropical frontiers, is infinitely more difficult, and other methods must be employed. So far as possible the soldier must be protected against (1) mosquito bites, (2) infection if bitten and (3) a possible long and fatal illness if infected. Reliance must be placed on (1) the correct selection of camp sites, (2) the spray-killing of adult mosquitoes with pyrethrum extract, (3) chemoprophylaxis with quinine and atabrine, (4) the use of nets and screens, (5) protective clothing, and (6) the organization and instruction of personnel. Of course, whenever

Fig. 5—Malaria rates in the U. S. Army in the continental United States during 1941 as compared with the ten year average and maximum and minimum months 1931 to 1940 (from U. S. Army Medical Museum negative 73220)

possible, anti-larval measures should be employed, but in many situations these are impractical because of the movement of troops.

CONCLUSION

It is of vital importance that line officers be alert to the disease hazards confronting their commands, and they must be advised by medical officers equipped with a full knowledge of these diseases. We must have medical officers with our forces who are adequately trained in the epidemiology, control and treatment of malaria. Only by the determined efforts of thoroughly trained officers can we hope to outwit and outfight the mosquito vectors of this disease. You can contribute to the safety of our armed forces by insisting that adequate instruction in tropical medicine be made a basic part of the undergraduate curriculums in every medical school in this country. By so doing you will raise the standard of medical education in America, you will strengthen our wartime defenses against malaria, and you will insure future progress in the Army's fight against this military plague.

Special Article

HANDBOOK OF NUTRITION· VI

PRINCIPAL MINERAL ELEMENTS IN NUTRITION

ICIE G. MACY, PH.D.

DETROIT

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—Ed

In a consideration of the mineral constituents of the body, one should bear in mind that, while these elements constitute only a small portion of the body weight, they enter into all the activities of the body to a much greater degree than their mere weight would indicate. For many years the important dietary components were stated to be protein, fat and carbohydrate, with slight emphasis placed on water and minerals; later, vitamins were added as necessary adjuncts. In the last few years, however, through voluminous records of physiologic investigations, the mineral elements have come into prominence and are now recognized as essential participants in practically every metabolic process carried on by the body.

The brief summary permitted in this presentation forbids reference to many significant studies of mineral metabolism. For the most part only studies which contain analyses of food, urine and feces for the seven principal minerals will be used as the basis of the present summary and discussion. This should not be interpreted to mean that investigations involving fewer elements have not contributed to a broader understanding and interpretation of the physiologic behavior of the whole group of elements, but reference to all the excellent reports which have appeared is unnecessary, since recently they have been compiled, integrated and interpreted in monograph form by Shohl¹ and ably summarized and cogently reviewed by Sherman².

For convenience and brevity the discussion is restricted primarily to consideration of the entrance of the principal mineral elements into the body, through the natural foods contained in a well balanced, mixed dietary; their retention and general use in the body and their exit by way of the urine and feces. Special emphasis is given to the interrelationship of the individual inorganic components in the construction and function of healthy tissue structure in infancy, childhood, adult man, pregnancy and lactation. Discussions of the relative values of different foodstuffs as sources of these nutrients will be covered in chapters dealing with the composition of foods and their nutritive value.

MINERAL COMPOSITION OF THE BODY

A large portion of the ash of the body is composed of calcium, magnesium, sodium, potassium, phosphorus, sulfur and chlorine. As these elements comprise from 60 to 80 per cent of all the minerals contained in the body, they may be considered as representing the principal minerals in nutrition. Table 1 illustrates the

¹ Shohl, A. T. *Mineral Metabolism*. American Chemical Society Monograph Series, New York: Reinhold Publishing Corporation, 1939.

² Sherman, H. C. *Chemistry of Food and Nutrition*, ed. 6. New York: Macmillan Company, 1941.

mineral content of the whole body at different ages. Aging up to adulthood, is accompanied by an increase in total ash, an increase in percentage of calcium and phosphorus and a decrease in magnesium, sodium, potassium, chlorine and sulfur. In accordance with Moulton's³ prediction on the chemical composition of man, the ash composition at birth represents approximately 3 per cent of the body weight.

Together with protein, fat, carbohydrate, vitamins and other chemical components, the principal minerals are essential to the structure or function of the body at any age or stage of development. Investigators during the past two decades have emphasized the important physiologic role of the principal minerals as individual entities in nutrition and pointed out that through their interrelationship with one another they may have even greater and far reaching significance in the process of life.

Approximately 99 per cent of the calcium,² 70 per cent of the phosphorus and magnesium and some of the sulfur, sodium and chlorine are involved in the construction or functioning of bone, with its cartilaginous organic matrix impregnated with mineral, while considerable quantities of phosphorus, potassium and sulfur are associated with nitrogen in the formation and activities of the muscle, glandular, neural and epithelial tissues. Sodium, potassium and chlorine and to a lesser extent the other elements are held in solution in the

varied widely for some elements less than 3 per cent, for others as much as 200 per cent or more.⁴ Because of the variations in the composition of foods and the differences in food habits of people, the body may not receive the proper quota of nutrients, even though the dietary is adequate according to published standards for food values.

The population may be divided into three groups, the well fed, the underfed and the misfed.

The well fed group receives a diet abundant in quantity and composed of a sufficient variety of foods to encompass all the essential food constituents in ample amounts and in desirable proportions to one another. This dietary meets the requirements of producing and maintaining a nutritionally stable body in the most efficient and satisfactory manner. The best diet need not be the most expensive one, as many of our most common and inexpensive foods possess nutritive superiority. The maintenance of a well balanced dietary from day to day is within the economic resources of every one but requires that foodstuffs be selected carefully, intelligently and thriftily to obtain the recognized essential nutrients in the most abundant amounts and most available form and that they be prepared and served in the manner which best preserves their dietetic value and renders them most easily digested and assimilated. An adequate food mixture which is digested readily and utilized satisfactorily is a prerequisite to buoant health and nutritive success.

The underfed group takes a diet insufficient in quantity to meet the minimal requirements of the body. Such a diet may result from limited economic resources, ignorance, indifference, disease or personal habits. The misfed group, through indifference, ignorance or faddism, chooses an unbalanced diet that will not permit the desirable synergistic effects of the food components during the physiologic processes of digestion and assimilation and subsequent utilization. The malnourished individual who has been underfed uses larger amounts of nutriment when his diet is improved, while the misfed actually may be inhibited from using certain materials until chemical adjustments have taken place within the tissues to a degree that will permit retention. Successful mineral metabolism, therefore, is conditioned by the absolute quantity of the individual minerals in the diet, the relative proportions among them and the inherent physiologic background and make-up of the person consuming the foods.

THE METABOLIC BALANCE

The term metabolic balance has been applied to the procedure of determining the quantitative intake of a food constituent over a given period of time, the corresponding quantitative outgo of that constituent in the feces and urine, and the calculation of the difference between intake and outgo. This difference is arbitrarily designated by the term retention when the intake is larger than the outgo and loss when outgo is larger than intake. While the metabolic balance procedure is a reliable method for observing the retention of minerals by living subjects, difficulties in interpretation arise from the fact that it is impossible to measure directly the loss of water and chemical substances through the skin, and there is no quantitative method of partitioning the fecal content into the amount representing unassimilated food residue, that which is of bacterial or glandular origin.

TABLE 1—Mineral Composition of the Body*

Age	Body Weight, Kg	Total Ash, Gm	Per Cent of Total Ash							
			Ca	Mg	Na	K	P	Cl	S	Total
Fetus 6 mos	0.88	19	28	0.9	10	7	17	8	8	79
Fetus 7 mos	1.16	30	23	0.8	8	7	14	10	6	69
Newborn	2.9	100	24	0.7	5	5	14	5	6	69
Adult	70	3,000	39	0.7	2	5	22	3	4	76

* Calculated from values given by Shohl.¹

body fluids, giving the intracellular and extracellular fluids their vital dynamic characteristics in the regulation of the p_H of the tissues, secretions and excretions, the osmotic pressure, electroneutrality, the distribution of the minerals in the body through the fluids, the irritability of the nerves and contractibility of the muscles, the permeability of the cells and general metabolism. The proper mixture or balance of the salt solutions in the body is of fundamental importance in maintaining the integrity of function of isolated cells and organs.

FOODS AND FEEDING

In order to meet nutritional needs satisfactorily, the consumption of each essential element must be sufficient to cover body losses and to provide a reserve for the formation of new body tissue when needed and for the integration of changing physiologic activities in growth and development. Foods vary in composition, the absolute and relative amounts of minerals in different foodstuffs depending on the kind of soil in which they are grown, climatic conditions, water supply and varying degrees of dehydration due to storage and handling. When the determined chemical composition of a number of foods commonly used in the average American diet, from samples collected under carefully standardized conditions at intervals over a period of seven years, were compared with the most recent summary of food values, the percentage differences of the average determined values from the standard tables

³ Moulton, C. R. Age and Chemical Development in Mammals. *J. Biol. Chem.* 57: 79-97 (Aug.) 1923.

and the amounts which result from direct excretion of products of metabolism into the intestine. Although all these factors must be recognized, the information obtained from metabolic balance investigation has broad application in nutrition and growth and yields valuable information about physiologic changes that occur with administration of specific dietaries and those that characterize certain pathologic states.

MINERAL METABOLIC BALANCES

With the metabolic balance procedure it is possible to determine with a high degree of accuracy the amounts of the principal minerals in the food, urine and feces. However, the retention values which are calculated by deducting the outgo in urine and feces from the food intake for a definite period of time, are less accurate, since some of the inorganic elements may be excreted through the skin. The magnitude of this recognized inherent error varies with each element depending on the amount of cutaneous loss. Recorded in the literature are relatively few metabolic balances which have been obtained on healthy individuals under standardized conditions and include simultaneous determinations of the seven electropositive and electronegative minerals.⁵ Table 2 presents the average daily intakes and retentions of calcium, magnesium, sodium, potassium, phosphorus, chlorine and sulfur, from studies considered comparable for infancy,⁶ childhood, adult man,⁸ the last six months of pregnancy⁹ and the first three months post partum.¹⁰

5 Many of the terms used by Shohl¹ in his attempt to clarify and to use specific terminology in that phase of nutrition dealing with mineral metabolism have been adopted.

6 Swanson W. W. The Composition of Growth. II. The Full Term Infant. *Am J Dis Child* 43:1018 (Jan) 1932. Schlutz F. W. Morse Minerva and Oldham Helen. Vegetable Feeding in the Young Infant. Influence on Gastrointestinal Motility and Mineral Retention. *ibid* 46:757-774 (Oct) 1933.

7 The average daily mineral balances have been taken from the mineral balance data recently published (Macy Icie G. Nutrition and Chemical Growth in Childhood. I. Evaluation. Springfield Ill. Charles C. Thomas. Publisher 1942). Since the data were accumulated on 29 healthy children aged 4 to 12 years under comparable experimental conditions during five hundred and ninety three five day periods (representing two thousand nine hundred and sixty five experimental days) they have been used primarily in tracing out the various paths and functions of the individual mineral elements and the total electropositive and total electronegative minerals in metabolism. The subjects received balanced diets containing ample amounts of minerals, vitamins and other essential nutrients. These longitudinal data are more reliable than cross sectional data since they encompass patterns of increment and rates of growth during consecutive intervals and at different ages. Dearborn and Rothney (Predicting the Child's Development. Cambridge Mass. Sci Art Publishers 1941 p. 147) have estimated that in the case of standing height the available longitudinal data on only 248 cases represent the equivalent of cross sectional measurements on 270,000 cases. Wilson (Heights and Weights of Two Hundred and Seventy Five Public School Girls for Consecutive Ages of 7 to 16 Years Inclusive. *Proc Nat Acad Sci* 21:633 1935) made similar estimates. Indeed it has been estimated that oxygen consumption and heat production measurements made on each of 10 children once a year for sixteen years a total of one hundred and sixty observations would give as much information about the way children grow or more than one observation on each of 2,500 children. (Talbot F. B. Wilson E. B. and Worcester Jane. Basal Metabolism of Girls. Physiologic Background and Application of Standards. *Am J Dis Child* 53:273-347 [Jan] 1937). Although the values for the different age groups are indicated in the original (Nutrition and Chemical Growth in Childhood. I) for this discussion I have considered only the average figures for childhood ages 4 to 12 inclusive to consider the individual age groups would lead to a consideration of chemical growth which is the subject of a treatise now in preparation (Macy Icie G. Nutrition and Chemical Growth of Children. II. Interpretation to be published).

Calcium—This is the element most likely to be deficient in the American dietary.¹¹ The lack of sufficient quantities of the mineral may have serious consequence on the longevity and fruition of the race.² Ninety-nine per cent of the calcium used by the body is concerned in bone and tooth structure, the remainder with the body fluids and soft tissues. With an average daily calcium intake of 0.72, 0.92 and 0.90 Gm for infancy (first year of life), childhood (4 to 12 years inclusive) and adult man there were average retentions of 0.14, 0.18 and 0.15 Gm respectively.

An individual experiencing rapid skeletal growth, having augmented physiologic demands or possessing a subnormal concentration of calcium in the bony tissue may require larger amounts of calcium in proportion to the need to develop a satisfactory physiologic state. Table 2 evidences that the amount of calcium required increases with age, growth and other physiologic demands that of pregnancy requiring the greatest amount. During the last half of pregnancy, which is generally accompanied by increased food consumption,¹² the calcium retained is used in replenishing the maternal bodily stores and in building new maternal tissues, to meet the increasing demands of the parasitic fetus the losses accompanying parturition, and in preparation of the maternal body to meet postpartum physiologic readjustment and the establishment of milk flow.¹³ A temporary increase in retention may follow an increased intake whereas a change in dietary calcium to a level lower than before may in itself induce a negative balance. It is known that some of the adult men whose balances are reported were on a low calcium diet preceding the experimental studies,⁸ perhaps this accounts for the comparatively large average daily calcium retention for men.

Individuals vary in their ability to utilize the calcium of their foods. Indeed Mitchell, Outhouse and their co-workers¹⁴ have emphasized that it is as necessary to know how well a person utilizes the calcium of the food which he eats as it is to know the actual calcium content of those foods. They found that preschool children and adults were able to use only one fifth to one fourth of the calcium in milk, but there were variations in the ability of the different individuals to use the calcium supplied. Certain vegetables tend to depress calcium utilization.¹⁵ The presence of vitamins C and D in the diet is essential in calcium utilization, similarly there are optimal levels of phosphorus and fat intakes in relation to the calcium consumed, which permit the calcium to be more completely utilized.

Calcium is largely excreted through the bowel. In the studies of normal children an average of 13 per cent of the mean daily output was eliminated through the kidneys and 87 per cent by way of the bowel. In terms of the calcium intake the mean excretion in urine and in feces amounted to 10 and 70 per cent, respectively, with a retention of 20 per cent. With an average daily intake of 0.92 Gm (46 milliequivalents) of calcium, 0.74 Gm (37 mEq) was excreted by the kidney and bowel and only 0.18 Gm (9 mEq) was retained.

Neither the most satisfactory level of calcium intake nor the optimal retention of calcium at any physiologic age or stage of man's development is known. Sherman and his students¹⁶ have shown that the calcium content of rat bodies at various ages was measurably influenced by the level of intake. To what extent such differences exist among human subjects remains to be determined.¹⁷ Perhaps the high vitamin content of the generous mixed dietaries, the healthy condition of the children and well filled body stores of calcium account for the mean daily calcium retention of 7.9 ± 6.8 mg per kilogram of body weight by the subjects, in contrast to the 10 and 12 mg estimated by Sherman,² Shohl,¹ and others.¹⁸ Perhaps the average run of children who grow up under less

the retained phosphorus combines with calcium, while nitrogen combines with the remaining 30 per cent. Phosphorus is essential in the metabolism of fats and carbohydrates, and participates in many phases of metabolism and in the regulation of the proper hydrogen ion concentration in the tissues, the secretions and excretions of the body. The form in which phosphorus is taken may have an important bearing on its nutritive value in the diet.²⁰

The average daily retention of phosphorus is increased from 99 mg in infancy to 264 mg by the twelfth year (table 2). In contrast to the 70 per cent average loss of calcium intake through the alimentary canal, only 31 per cent of the phosphorus intake was lost by that route. Fifty-five per cent of the phosphorus intake was excreted in the urine, 14 per cent was retained. The feces contained 29 to 40 per cent of the phosphorus output, and the remaining 60 to 70 per cent was lost from the body as metabolites in the urine. In the normal children, with an average daily phosphorus intake of 1250 ± 294 mg (72.8 mEq), 684 ± 152 mg (39.8 mEq) was excreted in the urine and 393 ± 112 mg (22.9 mEq) in the feces, 173 ± 175 mg (10.1 mEq) was retained.

§ Last half⁹

¶ First three months (Hummel, Sternberger, Hunscher and Macy¹⁰; Hummel, Hunscher, Bates, Bonner, Macy and Johnston⁹, Unpublished¹⁰). The balances obtained with lactating women are calculated by subtracting from the intake the output in urine, feces and breast milk. Only a small number of balances are available and these demonstrate wide variations in mineral retention ranging for calcium from an average of 343 mg daily to an average loss of 480 mg a day.

favorable conditions would need to store 10 to 12 mg per kilogram daily in order to attain optimal physiologic well-being. An average daily retention of 1 mg per kilogram of body weight for adult man and 9 mg during pregnancy are representative of the physiologic performance of the average healthy person.

There are numerous factors influencing the amount of calcium that the body may retain, for example physical and emotional activity, either directly or indirectly reflected through the gastrointestinal tract. Indeed, emotional disturbances may affect the elimination rate of both the kidneys and the bowels.¹⁹ A more rapid laxation rate (bowel movements per day) may stimulate a greater excretion of calcium through the feces.

Phosphorus—Phosphorus is widely distributed in the body, combined in many forms in soft and hard tissues and associated with protein, carbohydrate, fat, various minerals and organic substances. Seventy per cent of

Phosphorus is needed in relatively large quantities during growth because it is used so universally in the construction of skeletal, nervous and muscle tissues. Assuming that a relationship exists between body weight and phosphorus retention, during childhood when the average daily phosphorus intake amounted to 55 mg per kilogram of body weight, the average daily retention was 7 to 8 mg. During periods when the maternal body was being prepared to take care of the increasing demands of pregnancy, parturition and the establishment of lactation average daily intakes of 36 mg of phosphorus per kilogram of body weight resulted in average retentions of 4 mg. Adult man consumed on the average 11 mg of phosphorus per kilogram of body weight daily, of which 2 mg was retained.

The calcium to phosphorus ratio in the food intake has an important bearing on metabolism of both these elements.²¹ Phosphorus fed in excessive amounts causes a corresponding excretion of calcium in the feces, similarly, an increased intake of calcium leads to a greater output of phosphorus. On a unit weight basis, with a mean daily calcium phosphorus ratio of 1:1.4 in the

food intake during childhood the mean ratio was 1.71 in the urine, 1.61 in the feces and 1.01 in the retention. For the data compiled from the literature and presented in table 2, the mean calcium phosphorus ratios for the food intakes and retentions are presented in table 3. Since magnesium may replace some of the calcium required in metabolism, the calcium magnesium ratios are also given.

Not only is it essential to have liberal amounts of calcium and phosphorus in the diet, but these must be in the proper relationship to one another and be accompanied with a generous supply of vitamin D if skeletal tissue is to be constructed and maintained in a satisfactory manner.²² An inadequate and unbalanced diet with respect to calcium and phosphorus may result in rickets in the infant, calcium poor skeletal growth and possibly rickets in childhood, and osteoporosis or osteomalacia leading to fragility of bones in the adult. The severity of these conditions may be determined chemically by studies of the calcium and phosphorus content of the blood and clinically by roentgenograms of the bones.

Mellanby,²³ Schour and his co-workers²⁴ and Swanson²⁵ in teeth and Sontag²⁶ in the bones of infants have

shown that these tissues during formation are extremely sensitive to variations in metabolic processes, the alterations in internal environment of the body being recorded in the incremental layers, or rings, developing at the time. Environmental variations due to disease, to calcium and to vitamin C and D deficient dietaries affect the layers or rings formed at the time they occur. Whether dental caries is related to mineral metabolism remains questionable.²⁷

In general, an increase in calcium intake usually results in increased retention, but by a decreased percentage of the calcium intake retained. The calcium phosphorus ratio of the retention alters with age, young children retain more calcium in relation to their phosphorus retentions. The calcium phosphorus ratio in

the food also changes, as milk is supplemented with other foods (table 3). The variations in the composition of foods must be recognized, since the interrelationships among the quantities of minerals may be as important as or more important than the actual amounts of the single elements.

The body may not retain exactly what it needs and reject all other material, for it has great ability, known as homeostasis, to rearrange and adjust materials which it already possesses to meet current needs. An outstanding illustration of this capacity of the body is the mobilization of calcium from the long bones in the healing of rickets and, during gestation, to meet the needs of the fetus. It is obvious that some of the calcium and phosphorus constituting bone must be regarded as a reserve supply of calcium and phosphorus.¹ Moreover, the great flux of minerals in the blood, lymph, intracellular and extracellular fluids and the various secretions, such as saliva, gastric juice, bile and intestinal secretions, are in effect mineral reserves. Under conditions of ample intake there is a large storage of calcium during the last three months of pregnancy, but when the diet is inadequate in quantity and quality the demand exceeds the supply, and without the mobile reserves in the maternal bones the fetal demands could not be met.²⁸ Indeed, in many cases in which mothers are either underfed or misfed, both the mother and the fetus suffer severe consequences, depending on the extent of the dietary inadequacy and the degree of maternal reserves present.²⁹

It is now generally recognized that, although the feces do contain some material which has not been absorbed, they also contain material which has been absorbed and subsequently excreted into the alimentary tract. Large quantities of calcium in the food carry through the tract a large portion of the phosphorus which is ingested. A large intake of calcium may, in addition, cause phosphorus which previously has been absorbed, to leave the body by way of the feces rather than in the urine. Excess fat appearing in the feces in the form of soaps may likewise rob the body of calcium and other bases. It has been shown that under some conditions more calcium may be present in the feces than was ingested as food, which proves that some calcium must have been excreted into the intestine. Under long periods of inadequate calcium consumption the homeostatic capacity of the body is brought into play, and the body develops a characteristic ability for conservation of this element in its attempt to maintain physiologic functions compatible with life.³⁰ It is not possible at the present time to decide whether changes in metabolism of certain minerals such as calcium and phosphorus, which result in a greater or smaller amount being present in the serum or deposited in the tissues, depend on more effective absorption, increased excretion or improved deposition in the tissues.

Magnesium—In certain instances magnesium apparently has the ability to replace some calcium. About three fourths of the magnesium in the body is associated

with calcium in skeletal formation, and the remainder is present in the soft tissue and body fluids. Knowledge of its specific function in human nutrition is meager. Perhaps one of its most important functions in the body is serving in combination with organic radicals to form organometallic compounds³¹ which serve as catalysts in physiologic activities. Certainly the actual retention of magnesium by the body at any age is very small (table 2).

Like calcium, magnesium is excreted largely by way of the intestine. With children, of an average daily magnesium excretion of 250 mg only 35 per cent appeared in the urine and 65 per cent in the feces. Some of the erratic results obtained in metabolic studies may be due in part to unsatisfactory chemical procedures not generally recognized, for iron and other minerals are known to interfere with the accurate determination of magnesium in biologic materials. Using technics assuring accuracy of determination, the mean daily intake of magnesium during childhood amounted to 297 ± 42 mg (244 mEq), of which 88 ± 18 mg (72 mEq) and 162 ± 39 mg (133 mEq) were excreted in the urine and feces, respectively, and 47 ± 47 mg (39 mEq) was retained. An average of 16 per cent of the intake of magnesium was retained. Assuming a relationship of magnesium retention to body mass, with an average intake of 13 mg per kilogram of body weight in children, an average daily retention of 2 mg per kilogram occurred. In pregnancy an average of only 1.3 mg of magnesium per unit weight was retained, while there was practically an equilibrium in adult man.

Magnesium, calcium and phosphorus balances represent true values, since authoritative evidence³² indicates that no appreciable amounts of these substances are excreted through the skin.

Sulfur—A nutritionally essential element, sulfur has a far reaching significance in the body. It is a component of glutathione, insulin, thiamine and the organic matrix of the bone. Sulfur and nitrogen metabolism are closely related in protein metabolism. Only two naturally occurring sulfur containing amino acids (cystine and methionine) are known, and they account for a large portion of the sulfur consumed and utilized in the processes of metabolism. In previous studies of sulfur metabolism more emphasis has been placed on the sulfur paration in urine than on the balance between intake and outgo, especially in investigations with children.

In the studies reported for childhood the mean daily sulfur intake was 750 ± 130 mg, of this amount 79 per cent (593 ± 104 mg) was lost in the urine, 12 per cent (89 ± 26 mg) in the feces, and 9 per cent (68 ± 90 mg) was retained. Wide variations in the metabolism of sulfur are evidenced by the large standard deviation for the retention. These may be attributable to the fact that sulfur exists in several forms in the body, and the retention value includes any cutaneous loss of sulfur, which has been shown to be 60 to 106 mg of sulfate sulfur daily in adult man.³³

The average daily sulfur retention is increased with age from 8 mg in infancy to 144 mg for the 10 to 12 year group. In pregnancy there is an average storage of 205 mg of sulfur daily, but a loss may occur post partum (table 2). If, in man, one deducts the possible loss of sulfur through the skin, there is still a considerable storage of sulfur. In the men who provided the data considered in this review, nutritional status improved during the investigation,⁸ therefore it is possible that considerable sulfur was used in repair of old and building up of new tissue. It is possible also that there was a greater cutaneous loss of sulfur, since the experimental subjects were quite active during the investigation.

Assuming a relationship between body weight and sulfur retention, with an average daily intake of 34.2 mg of sulfur per kilogram of body weight at the 4 to 6 year level in childhood, there was a storage of 2.8 mg, at the 10 to 12 year level, the sulfur intake amounted to 28.8 mg and the retention 4.1 mg per kilogram of body weight daily. On a unit weight basis, adult man retained an average of only 1 mg of sulfur per kilogram of body weight and during the last half of pregnancy the average daily sulfur intake approximated 20 mg and the average retention 5 mg per kilogram of body weight daily. Recognizing the possible cutaneous losses, these results are in keeping with our present knowledge of physiologic changes that take place in normal pregnancy there is building of new tissue in the maternal body, in the enlargement of the uterus, in the mammary glands and in the body generally to take care of the augmented needs during labor and the losses during parturition and during the early days post partum, in lactation there is the physiologic readjustment of the body in the establishment of lactation, accompanied by the losses occurring with the involution of the uterus and other body organs and reserves.

Potassium—By virtue of its activity in relation to cellular water, potassium is associated with nitrogen metabolism. When new protoplasmic tissue is being formed, potassium is retained in sufficient quantities to meet the intracellular fluid needs of the newly formed cells. This alkaline mineral is held within the cells, although what activates and regulates its entrance into and its egress from the cells is not completely understood.¹ Irritability of the nervous system is dependent in large measure on the balance between calcium, potassium and sodium ions present in the tissues and the body fluids. A decided decrease in calcium increases irritability, and an increase in potassium will cause a similar effect. The proper mixture or balance among the salt solutions of the body is of fundamental importance for the maintenance of the integrity of function of cells and organs. The mobility and activity of the ions as they participate in the physiologic activity of maintaining electroneutrality and the distribution of minerals in bodily function are covered by another author.

There is an increased storage of potassium as growth proceeds. With average intakes of 1,016 and 2,776 mg of potassium in infancy and childhood there were mean daily retentions of 115 and 209 mg, respectively (table 2). Both pregnancy and lactation are accompanied by large potassium retention, averaging 639 and 526 mg daily, respectively. Adult man stores only a small quantity, 188 mg daily. On a unit weight basis

the retentions of potassium for adult man and women in pregnancy amount to 1 and 9 mg per kilogram of body weight a day, respectively

An average of 79 per cent of the intake of potassium was excreted by the kidneys, 13 per cent was excreted by the bowel and less than 8 per cent was retained in childhood. Of the mean daily intake of $2,776 \pm 437$ mg (71.0 mEq), $2,191 \pm 405$ mg (56.0 mEq) appeared in the urine, 376 ± 136 mg (9.7 mEq) appeared in the feces and 209 ± 268 mg (5.3 mEq) was retained. The large standard deviations accompanying these values illustrate wide differences in physiologic performance among individuals. The retention, which includes the cutaneous potassium loss, which may reach as much as 30 to 38 per cent, also evidences the approximate nature of these balances. If, however, 30 per cent of the retention value was lost through the skin, approximately 146 mg of potassium was retained by the children daily to meet body needs for growth and function.

Sodium—Although some serves as a part of the structure of the cartilage and muscle cells, sodium is associated with the blood plasma and the extracellular fluids. It functions largely with chloride and bicarbonate in control of the osmotic pressure and ionic equilibrium or electroneutrality of the body fluids and tissues. Considerably more sodium than potassium is needed in the body. The average daily retentions of sodium as determined for infancy, childhood and adult man amounted to 69, 246 and 1,382 mg daily, respectively. Of the total sodium excretion, 98 per cent may be eliminated in the urine and 2 per cent in the feces. This is to be expected since sodium is the most predominant positive mineral element in the extracellular fluids, circulates throughout the entire body and serves generally in the metabolic processes of the body in connection with the maintenance of electroneutrality.

The actual requirements of sodium and potassium are comparatively small, but the ratio between these two elements in the diet is considered of great practical importance. The high proportion of potassium to sodium in most common foods introduces two possible dangers, which may be evidenced metabolically by preventing full utilization of the sodium or by causing insufficient assimilation and utilization of other elements, especially calcium and phosphorus. Therefore, to compensate for the excess of potassium over sodium in foods and to enhance palatability, table salt is added to many foods incorporated in the daily diet. The body has a unique ability to conserve sodium in times of shortage and to absorb and distribute sodium rapidly when it is introduced into the body.

The mean daily intake of sodium by 29 children averaged $2,310 \pm 368$ mg (100.5 mEq), of which 787 mg was given in chemically pure sodium chloride. The average daily excretion of sodium in the urine amounted to $2,022 \pm 377$ mg (88.0 mEq), while a small but significant quantity (42 ± 39 mg, or 1.8 mEq) was eliminated through the alimentary canal, and 246 ± 280 mg (10.7 mEq) was retained. Assuming that 12 per cent of the retained sodium was dissipated through the skin,³⁴ the true mean daily retention of the children was 216 mg.

Chlorine—A component of all body secretions and excretions, chlorine is stored only to a limited extent, in the skin and subcutaneous tissue and in the skeleton.

The chlorides of the blood, particularly sodium chloride, compose about two thirds of the blood anions. They play an essential role in maintaining electroneutrality within the body and serve in large measure to maintain the osmotic pressure of the extracellular fluids. Gastric secretion contains chlorine in free hydrochloric acid and combined in salts. Chlorine, like sodium and potassium, is lost through the skin to the extent of about one fifth of that retained,³² hence the retentions in the metabolic balances presented in table 2 are exaggerated by that amount.

The average daily retentions of chlorine for infants, children and man amount to approximately 108, 277 and 1,063 mg respectively. Ninety-one per cent of the chlorine intake is eliminated through the urinary tract and only 1 per cent through the bowel. In children whose sodium chloride intake was controlled, the mean daily chlorine intake was $3,596 \pm 460$ mg (101.4 mEq), of which $3,265 \pm 467$ mg (92.1 mEq) was excreted in the urine, 54 ± 33 mg (1.5 mEq) was excreted in the feces and 277 ± 241 mg (7.8 mEq) was retained. Assuming that one fifth of the retention value represents cutaneous losses, the true retention value would be 222 mg of chlorine per day.

Human dietaries usually contain considerable quantities of sodium, potassium and chlorine and it is only during diarrhea, excess sweating and certain endocrine disturbances and metabolic conditions that an additional intake of these elements is required. Under ordinary conditions the body can adapt itself to shortages of these elements,³⁴ and it is generally assumed that a diet which is adequate in all other respects will contain amounts sufficient to meet the nutritive demands. It is recognized, however, that the adjustment of the body to a change in level of intake of sodium, and of potassium in particular, requires longer than the conventional week or ten days, and that excessive proportions of potassium in diets may prevent full utilization of sodium by the organism and may cause insufficient utilization of calcium and phosphorus.

Minerals are lost from the body during acidosis. The growing child is particularly prone to acidosis, especially when consuming high fat diets. In a controlled metabolic balance study which included the determination of the seven positive and negative minerals and nitrogen Sawyer, Baumann and Stevens³⁵ observed 2 children aged 5 and 8 years during the consumption of a normal diet and subsequently when the lactose and sugar of the normal period were replaced by an isodynamic quantity of pure butter fat. The mineral, nitrogen and calory intakes remaining the same during the two observation periods. The high fat diet caused increased acid production in the body which resulted in increased elimination of nitrogen, sulfur, calcium, magnesium, phosphorus, sodium, potassium and chlorine. It is assumed that the nitrogen and sulfur were derived from catabolized muscle, calcium, phosphorus and magnesium were of skeletal origin, and sodium, chlorine and potassium were obtained from body fluids. The losses, particularly calcium and phosphorus, varied directly with the severity of acidosis.

POSITIVE AND NEGATIVE MINERAL BALANCES

The electropositive minerals (calcium, magnesium, sodium and potassium) and electronegative minerals (phosphorus, sulfur and chlorine) serve singly and in combination in the physiologic structure and function of the body. As food burns in the body, the organic anions, citrates, acetates and so on are completely oxidized, all of the positive mineral elements and the negative element chlorine are released, and the negative minerals sulfur and phosphorus are generally assumed to be completely oxidized to phosphates and sulfates. However, the anion values of sulfur and phosphorus retained in the body may have several valences, since they enter into combination with other elements to form many different compounds. In calculating, the average valence of 1.8 has been assigned to phosphorus and a valence of 2 to sulfur.³⁶

* A valence of 1.8 has been used for phosphorus and 2 for sulfur although it is recognized that these are only approximations. No deductions have been made for cutaneous losses.

† Retentions were calculated as intake minus output in urine, feces and breast milk.

During growth and body repair there is an accumulation of both positive and negative minerals in the tissues, the total amount depending on the intensity of the physiologic processes. The relationship between the gross amounts of positive and negative minerals retained is determined by the relative demands for materials with which to construct hard and soft tissue and by the cutaneous losses of potassium, sodium chloride and sulfur. Table 4 presents the average intakes and retentions of the total positive minerals, total negative minerals, total positive plus negative minerals and excess of positive minerals for infancy, childhood, adult man, pregnancy and lactation.

Skeletal tissue synthesis creates a demand for positive minerals, soft tissue construction requires a preponderance of negative minerals, therefore increased retentions of positive minerals in relation to negative minerals indicates an impetus to skeletal construction and the reverse shows an emphasis on soft tissue formation. The retention of positive, negative and total minerals is increased from infancy through childhood to

adulthood, but the average daily retentions per kilogram of body weight decrease. While pregnancy demonstrates augmented metabolic demands for all minerals, metabolic balances concurrent with early lactation may demonstrate a loss of negative minerals commensurate with the tissue involution taking place in the uterus and other maternal organs and the peculiar physiologic demands of lactation. When considered on a unit weight basis, growth and pregnancy are accompanied by a retention of total minerals and excess positive minerals, but during lactation these occur to a lesser extent than in adult man. A retention of total minerals is one of the best criteria that growth, repair or repletion are taking place.

The positive and negative minerals constitute approximately 25 per cent of the total urinary solids of children. Although the diet may be constant in quantity and quality, the amounts of positive and negative minerals excreted from day to day depend on current metabolic demands for growth or maintenance. An average of 156 mEq of mineral cations and 169 mEq of mineral anions were excreted in urine by normal children. These, together with the nonmineral cation NH_4^+ , the titrable acidity and the organic acids, determine the acidity or alkalinity of the urine. In the feces of the children, the positive and negative minerals together composed approximately 10 per cent of the total fecal solids. An average of about 7 per cent of the total weight of the fecal solids consisted of positive minerals. Calcium, magnesium, potassium and phosphorus compose the greater part of the minerals eliminated in the feces, but relatively small amounts of sodium, sulfur and chlorine are present.

The electropositive minerals (calcium, magnesium, sodium and potassium) are especially important in skeletal formation, particularly calcium and magnesium, in nervous and muscular activity and blood coagulation. Sodium and potassium participate in the control of body water as well as in other structural and functional activities. In childhood the average daily positive mineral content of the diets was 242 ± 40 mEq, of which 29 ± 22 mEq was retained. The average daily positive mineral content of the feces was 57 ± 14 mEq, 56 per cent of which was calcium. The average daily consumption of positive minerals per kilogram of body weight was 107 ± 16 mEq. On the same basis 69 ± 10 mEq was excreted in the urine, 25 ± 0.7 mEq was eliminated in the feces and 13 ± 0.9 mEq was retained.

The average daily intake of electronegative minerals (phosphorus, sulfur and chlorine) in childhood was 221 ± 37 mEq, of which the kidneys excreted 169 ± 26 mEq and the intestine 30 ± 8 mEq while 22 ± 20 mEq was retained. Approximately 85 per cent and 15 per cent of the excretion of the negative minerals take place in the urine and feces, respectively, in comparison to 73 per cent and 27 per cent, respectively, for the excretion of positive minerals. On the basis of body weight an average of 98 ± 1.4 mEq of total negative minerals was consumed and only 10 ± 0.8 mEq was retained per kilogram daily.

EXCESS MINERALS

When the quantity of positive minerals exceeds the quantity of negative minerals or the negative exceeds the positive, the excess for the food intake is designated by the terms alkaline-ash and acid-ash value respec-

tively, for the urine and feces the values are given as the excess of positive or negative minerals. The alkaline-ash values of the diets and the excess positive minerals retained by infants, children and man, in pregnancy and in lactation are shown in table 4 daily and daily per kilogram of body weight. All diets had an alkaline-ash value, though that of adult man was lowest (10 mEq). The value for the diets of infants and children ranged between 21 and 24 mEq, and in pregnancy and lactation the amounts were 99 and 98 mEq daily. A retention of cations in excess of anions occurred at all ages, on a unit weight basis there was an average daily retention per kilogram of 0.3 mEq for childhood, 0.1 mEq for man, 0.4 mEq for pregnancy and 0.5 mEq for lactation.

Retentions of both positive and negative minerals are essential to growth. Normally the body requires a very slight excess of total positive over total negative minerals but greater excess positive mineral retentions indicate an emphasis on skeletal growth or an augmentation of mineral storage in bony tissue. Retention from the dietary of an excess of negative minerals indicates that formation of muscular, glandular and neural tissues is proceeding at the faster rate.

The amount stored of any one or all of these inorganic elements is influenced by the composition of the food and the current nutritive needs of the individual. The amount of each element ingested, the proportion of one element to another, the fat and other components of the diet—all are determining factors in metabolism and utilization of the positive and negative minerals. Indeed, the proportions of individual members of the positive and negative mineral groups in the diet may have more importance in general metabolism during growth than the total or excess quantities of the two groups of elements.³⁷

Some foods or conditions may cause a change in the path of excretion from urine to the feces, that is, an increased output of calcium in the feces may be compensated by a decrease in output of calcium in the urine. The mineral elements which seem to be most susceptible to exchange between the urine and feces are calcium, phosphorus, sodium, potassium and chlorine. Cutaneous losses of potassium, sodium, chlorine and sulfur may cause a significant cumulative error in the retention values. With proper recognition of these possible inherent errors, metabolic balance data including the quantitative chemical determination of the positive (calcium, magnesium, sodium, potassium) and negative minerals (phosphorus, sulfur, chlorine) in the food over a given period of time, and the quantitative outgo of these constituents in the feces and urine give valuable information concerning the physiologic activity in the body. The calculation of the difference between intake and outgo in the urine and feces, although in some cases it may be of an approximate nature, gives significant information on the metabolism of the individual elements and groups of minerals during the various stages of growth and physiologic function and render valuable service in the diagnosis and treatment of certain types of diseases.

Council on Industrial Health

MEETING OF THE COUNCIL ON INDUSTRIAL HEALTH

The tenth meeting of the Council on Industrial Health was held at the Hotel Traymore in Atlantic City, N. J., June 7, 1942. Those present included Stanley J. Seeger, Chairman, Harvey Birtle, Leverett D. Bristol, Warren F. Draper, Philip Drinker, Leroy U. Gardner, Raymond Hussey, Anthony J. Linza, Robert T. Legge, Clarence D. Selby, William D. Stroud and Carl M. Peterson, Secretary.

PROFESSIONAL RELATIONS

Steps taken to develop and maintain interest in industrial health in state counts and special medical societies were reviewed by the Committee on Professional Relations. Additional discussion demonstrated that contact with state committee personnel, officers of state medical societies and other influential people was more important now than ever before and that effort should be made to augment this activity if possible. It was recommended that additional assistance should be secured if agreeable to the Board of Trustees.

The association of the chairmen of the Council as consultant to the Division of Industrial Hygiene, U. S. Public Health Service, was described in expectation that this type of organization would stimulate medical society cooperation and activity as well as improve associations between physicians and the personnel and programs of industrial hygiene bureaus in state health departments.

The growing interest in industrial health by the sections of the Scientific Assembly was viewed with great favor. Several of these cooperating committees have regarded some of their problems as common to all specialties and it seems likely that a method of group consideration and subsequent recommendation to the Council could be adopted.

EDUCATION AND PUBLICATIONS

The Committee on Education and Publications emphasized particularly the urgency of postgraduate instruction. It was realized that, in making plans for such training, full account would need to be taken of the shrinking medical population and the enormous additional burden thrust on physicians in community practice.

Plans for better training of health officers in the essentials of industrial hygiene were described as an additional approach to adequate handling of certain medical requirements in industry and as a means of acquainting the general profession in better fashion about acceptable industrial health methods.

The Council noted that Dr. C. D. Selby had been added to the joint committee to investigate certification of industrial practitioners as a representative of the American Association of Industrial Physicians and Surgeons. The considerable difficulties attached to such a program were discussed.

The Committee on Occupational Dermatoses of the Section on Dermatology and Syphilology will be asked to review the necessity for a concentrated drive on dermatitis in industry as a direct contribution to reducing lost time in industry and to prepare useful educational material for the publications program of the Council.

PHYSICAL EXAMINATIONS

The Committee on Physical Examinations presented a tentative outline intended to conform as closely as possible to the American Medical Association manual on Periodic Health Examinations. After extensive and critical review it was agreed that the committee present a revised draft to the Council at the earliest convenient time.

OCCUPATIONAL DISEASE REPORTING

The same difficulties previously reported about securing accurate information relative to occupational disease incidence con-

37 Macy, Icie G., Hummel, Francis C., Hunscher, Helen A., Shepherd, Marion L., and Souders, Helen J. Effects of Simple Dietary Alterations on Retention of Positive and Negative Minerals by Children. *J. Nutrition* 19: 461-476 (May) 1940.

tinue to operate. A number of recommendations for continued activity and greater improvement of reporting included

- (a) Better collaboration between health departments and industrial commissions
- (b) Improved financial support for the preparation of statistical studies by workmen's compensation authorities
- (c) Better cooperation from physicians in reporting occupational diseases

Attention was called to an improved form for tabulating compensable conditions developed by the U S Department of Labor. It was also suggested that the Council and other interested agencies begin to urge on the Bureau of the Census that a tabulation of deaths by occupation be made available as soon as possible.

WORKMEN'S COMPENSATION

The Committee on Workmen's Compensation reported that conferences had been held recently with insurance executives to discuss medicoinurance relations, such as supervision of medical service, organization of medical departments in insurance companies, medical field work and the procurement of physicians to undertake insurance and compensation practice in various localities. These conferences made it clear that further contact is necessary if an effective medicoinurance program is to be developed. Representatives of stock and mutual casualty insurance companies meet regularly for the discussion of rates and claims. In this joint conference there is a subcommittee on medicine. It is hoped that working relations can be established with this committee after additional informal discussions have occurred with top executives.

The committee has also held conferences with representatives of the Bureau of Labor Standards in the U S Department of Labor and with executive officers of organized labor groups in Maryland. As far as can be readily determined, labor has made few attempts to formulate a definite health and medical program.

In spite of many surveys made on the operation of workmen's compensation laws, few pertinent medical data are available. It is not only desirable but highly important that such data be obtained. It is particularly true in those states where medical boards have been appointed in connection with the administration of occupational disease laws. The committee emphasized the need for acquainting state medical societies with the medical aspects of compensation legislation, since it is highly probable that these laws will be revised or expanded in many directions shortly. In the same way, a genuine effort should also be made to have properly qualified physicians hear testimony on controverted medical issues. Medical boards attached to compensation commissions appear to be an effective solution, and thought should be given to methods of organization and personnel of such boards. Medical societies also should be encouraged to study medical testimony in courts of law and quasijudicial administrative bodies with a view toward establishing methods of investigating questionable medical evidence. They should also be stimulated to maintain contact with industrial commissions through appropriate committees. The committee called attention again to the controversy in occupational disease legislation between schedule versus general coverage types of laws. It is desirable that the Council develop and express an opinion on this subject from a purely medical point of view.

In recognition of the fundamental importance of the report, the Council agreed that the committee be enlarged through the appointment of additional members and by the creation of advisory personnel representative of law, insurance, labor and other affected interests. The relation of this committee to other agencies in the American Medical Association, particularly the Bureau of Legal Medicine and Legislation and the Bureau of Medical Economics, should be clarified as well as with such other medical organizations as the National Tuberculosis Association, the American Heart Association and others as found desirable. The Council instructed the committee also to call the attention of the state medical societies to the need for a review of methods to control medical testimony and to engage at once in the preparation of articles on prevailing medical opinion about industrial disability.

RESEARCH

The Committee on Research was instructed to investigate those aspects of industrial medical experience most urgently in need of review and to develop recommendations calculated to encourage specific studies. Programs of the committees on industrial health in the sections of the Scientific Assembly in particular were thought to hold great promise if pursued in this direction. Particular attention also should be given to problems of industrial health administration and the rehabilitation and utilization in industry of handicapped persons.

INDUSTRIAL HEALTH AND THE WAR

The Council heard reports presented by the Subcommittee on Industrial Health and Medicine, the Division of Industrial Hygiene in the National Institute of Health, the Industrial Hygiene Division of the Medical Corps of the U S Army, and the Procurement and Assignment Service. These reports confirmed the impression that the medical profession is increasingly aware of the importance of industrial health but that there are great and unsolved problems still to be met before physicians find themselves in good position to respond to greatly increased demands for industrial medical service.

INDUSTRIAL NURSING

The representative of the Council on the Committee to Study the Duties of Nurses in Industry of the American Public Health Association reported that this survey was still in progress. The Council also reviewed a request for the publication of a pamphlet for the guidance of industrial nurses along lines previously followed by the State Medical Society of Wisconsin.

NUTRITION IN INDUSTRY

A joint committee representing the Council on Foods and Nutrition and the Council on Industrial Health was organized to consider scientific problems arising in the field of nutrition in industry, to study available evidence and to bring to the attention of the profession at large prevailing opinion on adequate nutrition of industrial employees. Members appointed on this committee were

Representing the Council on Foods and Nutrition, James S. McLester, George R. Cowgill and Russell M. Wilder.

Representing the Council on Industrial Health, Leverett D. Bristol, Clarence D. Selby and William D. Stroud.

INDUSTRIAL MEDICAL SERVICE PLANS

Attention was paid to types of medical organization available to industrial workers and their families in ordinary as well as boom areas, and with special reference to those medical service plans now being developed by state and county medical societies and by labor unions. Subsequent studies will determine to what extent these and other experiments are meeting the existing demands for redistributing available medical personnel and facilities.

INDUSTRIAL MEDICAL ORGANIZATIONS AND CIVILIAN DEFENSE

The Council recommended that the Office of Civilian Defense be asked to issue a manual of instructions for physicians in industry and that specific plans of individual industrial organizations for medical management of catastrophes be given publicity if of sufficient merit.

WOMEN IN INDUSTRY

The formation of a subcommittee on the Health of Women in Industry was discussed. It was also agreed that women physicians could play a very useful role in industrial medical organization.

AVIATION MEDICINE

The Council created a committee to consider the advisability of a program in aviation medicine for application to ordinary industrial, test flight and transportation problems as opposed to purely military aspects and having in mind the establishment of proper relationships with the activities now occurring in the National Research Council along the same lines.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE USE OF BULK ETHER HAS PERIODICALLY RAISED CONSIDERABLE CONTROVERSY AMONG THE MEDICAL PROFESSION AND ALLIED SCIENCES IN VIEW OF THE PRESENT EMERGENCY AND EXISTING SHORTAGES IT SEEMED TIMELY TO REVIEW THE STATUS OF THIS AGENT. AT THE REQUEST OF THE COMMITTEE ON DRUGS AND MEDICAL SUPPLIES OF THE DIVISION OF MEDICAL SCIENCES OF THE NATIONAL RESEARCH COUNCIL THE COUNCIL ON PHARMACY AND CHEMISTRY ARRANGED FOR THE PREPARATION OF THE FOLLOWING REPORT BY DR. HARRY GOLD. WHILE THE AUTHOR MENTIONS BULK AMOUNTS OF ETHER UP TO THIRTY POUNDS IT SHOULD BE POINTED OUT THAT U. S. P. XII STATES ETHER TO BE USED FOR ANESTHESIA MUST BE PRESERVED IN TIGHT CONTAINERS OF NOT MORE THAN 3 KG. CAPACITY. THEREFORE IT WOULD BE ILLEGAL TO SHIP ANESTHESIA ETHER LABELED FOR ANESTHESIA IN CONTAINERS WHICH CONTAIN MORE THAN THIS AMOUNT.

AUSTIN E. SMITH, M.D., Acting Secretary
COUNCIL ON PHARMACY AND CHEMISTRY

THE USE OF BULK ETHER IN ANESTHESIA

HARRY GOLD, M.D.
NEW YORK

The belief that ether for anesthesia should be stored in small containers and that it should not be used for anesthesia twenty-four hours after the containers are opened dates back to the work of Baskerville,¹ who was the first to study extensively the conditions under which ether deteriorates. The foregoing was, in fact, his recommendation embodied in the United States Pharmacopeia during a period of about thirty years (U. S. Pharmacopeia IX, X, XI). The advice has been widely accepted and hospitals have pursued the practice of purchasing anesthetic ether in large numbers of one-quarter and one-half pound sealed metal cans. What remained after the first twenty-four hours was used for cleansing or other purposes.

In 1934 a study was published by Harry and David Gold² which challenged the validity of the twenty-four hour clause. It was shown that in ordinary anesthetic ether cans which were opened many times and stoppered with cork, the contents remained pure by very delicate chemical tests for the usual impurities aldehydes and peroxides, during periods of months. It was clear from this that the common belief that ether deteriorates quickly when the can is opened is an error. In a subsequent study by Hediger, Chenoweth and Gold³ it was further shown that ordinary laboratory cork did not promote oxidation of ether by the fact that, when the ether was stored with ground-up cork in the can, the ether retained its purity over periods of several weeks. The cork stopper, therefore, presents no source of trouble. The possibility that ether might deteriorate if the stopper was accidentally applied too lightly, so that air had free access to the ether, was tested by placing the stopper on the ether can so lightly that the ether evaporated in a period of several days. Under these conditions it remained free of aldehydes and peroxides to the last.

In spite of the fact that these studies showed that ether taken from large containers (up to 30 pound drums) which had been opened and stoppered with

cork during periods of months developed no chemical changes, anesthetists were reluctant to use such ether routinely for anesthesia. Such practice ran counter to tradition. If chemical tests couldn't distinguish bulk ether from ether in small cans freshly opened, could the anesthetist tell them apart by the reaction of patients? This was tested during a two year period at the New York Hospital in a series of 2,500 surgical cases. The reader may consult the original papers by the Golds,¹ by Hediger and Gold² and by Hediger, Chenoweth and Gold³ for the details of these studies. Suffice it to say that when anesthetists were in the dark as to the source of the ether they couldn't distinguish, by the effect on their patients, ether in freshly opened small cans from ether in large drums which had been opened and stoppered with cork during periods of several weeks. A similar study carried out by Dooley and others⁴ in Syracuse yielded similar results.

The suggestion issued⁵ that hospitals abandon the purchase of ether in small one-quarter or one-half pound containers, and instead purchase anesthetic ether in bulk, in containers of 5 to 30 pounds. It was emphasized that the ether placed in the large container should be of the same high quality as the anesthetic ether now supplied in small sealed cans. There followed a storm of protest mainly from industrial sources. The cost of ether in bulk is only about one-fifth that in small containers.

The routine use of ether in bulk for anesthesia has been adopted in many hospitals of various sizes throughout the United States. We have information about this from one or more hospitals in New York, Baltimore, Boston, Syracuse, Rochester, Cleveland, Battle Creek, Ann Arbor and Chicago. The list is not complete. Some of these hospitals have now been using ether in bulk for anesthesia without encountering any difficulties during a period as long as five years. A survey made by Snoke⁶ in 1941 disclosed that "all of the hospitals that are using bulk ether in 5 or 30 pound drums are satisfied that the quality of the ether is satisfactory." Some test the ether for aldehydes and peroxides by the U. S. Pharmacopeia tests before issuing the duly supply of small cans. Others have abandoned the testing, since long experience has shown it to be unnecessary.

The Twelfth Revision of the U. S. Pharmacopeia has sanctioned the practice by the revision of the article on ether. According to the new text, official ether for anesthesia may be stored in containers as large as 3 liters. Furthermore, the Pharmacopeia no longer considers ether unsatisfactory for anesthesia twenty-four hours after the container in which it is supplied is opened, it places no limit on the period of time in which ether remains fit for anesthesia after the container is opened. As will be discussed presently, the container into which the ether is transferred is a matter of great importance. The Pharmacopeia guards against

the danger from the transfer to containers that may not be suitable by directing that ether should not be used for anesthesia after it has been removed from the original container longer than twenty-four hours.

The need for the transfer of ether from large containers into smaller ones by the hospital pharmacist has focused attention on the fire and explosive hazard of the handling of ether. These hazards have been summarized in a bulletin of the National Board of Fire Underwriters.⁹ It is well known that ether is inflammable in the form of its liquid and vapor. In suitable mixtures with air (1.85 to 36.5 per cent of the vapor in air by volume) it burns or explodes. The vapors are heavier than air. They tend to settle near the floor and establish islands of ether or flow in a stream through crevices under the door and down the stairs. Ignited at any point, the stream will propagate the flame for considerable distances. Contact of the vapors with flame, a static or friction spark or any object heated to the appropriate temperature may cause fire or explosion.

These hazards, however, have long been known and apparently are sufficiently well appreciated by the average hospital pharmacist so that fires and explosions from the transfer of ether as handled by the hospital pharmacist are extremely rare. Snoke,⁸ assistant director of the Strong Memorial Hospital of Rochester, points out that "almost every hospital pharmacy stocks ether, alcohol, acetone and gasoline in bulk and repackages them in small containers to be distributed to the wards and laboratories for various uses. The transferring of 5 or 30 pounds of ether into small containers does not present much more fire hazard than now actually exists in any pharmacy." In this connection Clarke¹⁰ chief pharmacist of the New York Hospital, states that "principally as a result of adopting the use of bulk ether for anesthesia" the pharmacy personnel acquired more respect for the hazards of handling ether and a more efficient technique for avoiding those hazards than used to be the case when bulk ether was used only for cleansing and solvent purposes.

The containers in which ether is issued to the operating room may be the tins in which anesthetic ether is supplied in commerce. They must first be thoroughly rinsed with the fresh ether with which they are to be filled. A special copper can may be made. The specifications for such a can have been described by Clarke.¹⁰ The container is a matter of great importance. Amber colored bottles are fairly satisfactory, but they present the danger of breakage. Clear glass bottles cannot be used, since the exposure of ether to sunlight leads to fairly rapid deterioration.

The transfer of ether from a 5 pound can or a 30 pound drum into the smaller containers is managed differently in different hospitals. The details of the technique employed at the New York Hospital have been described by Clarke.¹⁰ The transfer may be effected by means of a clean glass funnel. In the case of 30 pound drums, a copper siphon arrangement as described by Clarke is very useful. The procedure should be carried out in a room free of flames or burners and free of mechanical moving parts which may be a source of sparks. Free ventilation is necessary. The larger the room the less the danger of developing an explosive mixture of ether vapor with air

during the process of the transfer. This danger generally speaking, is extremely small. The National Board of Fire Underwriters⁹ states that the vapor from a quarter pound of ether will make 60 cubic feet of air explosive. This is approximately the minimal explosive concentration of ether vapor in air. We produced such an atmosphere in a laboratory room and found it almost unbearable for more than a few moments to several individuals who entered. One third of the minimal explosive concentration of ether vapor imparts a very strong odor of ether to the atmosphere. Dangerous quantities of ether vaporized during the transfer are not likely to escape the notice of the pharmacist. An atmosphere in which the odor of ether is faint is not explosive. The transfer of a 5 pound can of ether into small containers in a room of about 2000 cubic feet would not produce an explosive atmosphere even if the entire quantity escaped in the form of vapor evenly distributed throughout the room.

The safety of bulk ether for surgical anesthesia appears to be established. The danger of the transfer from large to small containers by the hospital pharmacist, if the foregoing precautions are observed, is negligible. Snoke⁸ suggests that ether in 5 pound tins or 30 pound drums is practical only in institutions that use a considerable amount of ether, namely those that have a weekly ether consumption of more than 5 or 10 pounds. The financial saving is considerable. Clarke¹⁰ states that "a hospital may reduce its ether for anesthesia bill by between 68 to 78 per cent—a striking thought when it is realized that a million dollars' worth of ether was sold last year in small containers specially labeled for anesthesia." The wider application of this practice may be of particular importance in the present state of the nation, with the urgent need for economy in labor and in metal.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Acting Secretary

THIAMINE HYDROCHLORIDE (See New and Non-official Remedies 1941, p. 551)

The following dosage forms have been accepted
GEORGE A. BREON & CO., INC., KANSAS CITY, MO.
Tablets Thiamine Hydrochloride 1 mg. and 5 mg.

DEXTROSE (See New and Nonofficial Remedies, 1941, p. 179)

The following dosage forms have been accepted
GEORGE A. BREON & CO., INC., KANSAS CITY, MO.
Ampul Solution Dextrose 50% (W/V) 20 cc
FLINT, LATON & COMPANY, DECATUR, ILL.
Ampul Solution Dextrose 50% (W/V) 50 cc and 100 cc

NICOTINIC ACID (See New and Nonofficial Remedies, 1941 p. 555)

The following dosage form has been accepted
FLINT, LATON & COMPANY, DECATUR, ILL.
Tablets Niacin 25 mg.

NICOTINIC ACID AMIDE (See New and Nonofficial Remedies 1941, p. 556)

The following dosage forms have been accepted
DRUG PRODUCTS CO., INC., LONG ISLAND CITY, N. Y.
Ampul Hyposol Solution of Nicotinamide, 50 mg. per cc. 1 cc
Hyposol Solution of Nicotinamide, 50 mg. per cc. 10 cc vial Preserved with 0.5 per cent of chlorobutanol
FLINT, LATON & COMPANY, DECATUR, ILL.
Tablets Nicotinamide 50 mg.

SATURDAY, SEPTEMBER 5, 1942

CONGRATULATIONS TO THE BUREAU OF MEDICINE AND SURGERY OF THE NAVY

On Monday August 31, the United States Navy celebrated the one hundredth anniversary of the establishment of its Bureau of Medicine and Surgery by dedicating the new Navy Medical Center at Bethesda, Maryland. The proceedings included an international broadcast by five networks, symbolic of the worldwide scope of the work of this department of the Navy. The ceremony was featured by an address of President Franklin Delano Roosevelt and included messages to naval installations in Iceland, Ireland, Honolulu and Panama, with responses from Capt Brython P Davis, commanding officer of Destroyer Base Hospital No 1, North Ireland, Capt J J McMullin, commanding officer of the Pearl Harbor Naval Hospital, Capt Lewis W Johnson, senior naval medical officer in Iceland, and Capt Howard F Lawrence of Panama. No celebration is contemplated at these remote points where the Navy is actively in service.

The motto of the United States Naval Medical Department is

**To keep as many men at as many guns as
many days as possible**

The career of the United States Naval Medical Department over the century has been marked by many brilliant episodes, including several instances in which Naval medical officers took over command following the deaths of officers of the line. For example, a naval medical officer, Dr Richard C Edgar, was the recipient of those famous lines of Captain Lawrence, destined to become the motto of the Navy, "Don't give up the ship."

The first chief of the new Bureau of Medicine and Surgery in 1842 was William Paul Crillon Barton of Philadelphia. Rear Admiral Ross T McIntire is twenty-third in a long line of surgeon generals of the Bureau of Medicine and Surgery of the Navy.

In the early days of the Navy a ship's surgeon received twenty-five dollars a month and had the status of a hired hand. Today naval medical officers achieve high rank and are engaged in a multitude of scientific activities representative of the finest advancement of medicine. The functions of the medical officers of the Navy include research on problems related to ships, airplanes and land warfare. Already notable contributions have been made on submarine warfare, aviation, treatment of burns, the effects of blast and the control of many types of epidemic disease. Naval medical officers have designed hospital ships, invented new appliances and contributed magnificently to research in internal medicine and in surgery.

A century ago the headquarters of the Bureau of Medicine and Surgery included a chief, an assistant chief and two clerks. Today the expanded Navy includes many hundred thousands of men and thousands of medical officers and medical personnel. Its responsibilities for medical care include the Marine Corps and Coast Guard as well as itself.

The first century has been one of great achievement and high scientific endeavor. To the Surgeon General of the Navy, Rear Admiral Ross T McIntire, and to the men whom he leads, our congratulations.

JAUNDICE IN THE ARMED FORCES

Elsewhere in this issue (page 51) appears an official statement from the United States Army Medical Department, in the form of a circular letter issued to all medical officers, reporting on the cases of jaundice which occurred among our troops, apparently related to vaccination against yellow fever. This statement, issued promptly by the Army Medical Department, will make clear to those capable of reading it understandingly the problems that are concerned and the manner in which the Army Medical Department is studying them.

Last week the *Chicago Tribune*, apparently having revised its old motto to read

"The *Tribune*, right or wrong, but right or wrong, the *Tribune*."

persists in its attack on the Army Medical Department in association with this incident. THE JOURNAL has indicated previously its belief that the attack is unwarranted, that it will tend to undermine military and civilian morale and break down confidence in scientific medicine. Fortunately, the *Tribune* seems to be quite alone in the attack and in the persistence.

In the course of its editorial the *Tribune* makes a number of misstatements of fact which are here corrected. The *Tribune* states

"It appears in dispatches from Washington that the Navy, using a vaccine prepared according to a different formula, had had no such record of deaths and illness as the Army has disclosed."

This is untrue! The Navy used the same vaccine that was used by the Army, inoculating over 100,000 men and having a considerable number of cases of jaundice although, of course, not as many as occurred in the Army. The United States Public Health Service used the same vaccine in thousands of cases and also had cases of jaundice. Thus far there have been no reports of deaths from this cause in the Navy. It must be remembered, however, that naval units are much smaller, that they are operating at tremendous distances and that reports of illness come in more slowly, although deaths are reported immediately.

The *Tribune* states

"The probability is that the error of judgment was not committed by Maj. Gen. James C. Magee, the Surgeon General of the Army, for he is said to have been opposed to the wholesale vaccinations against yellow fever. Evidently whoever was to blame is to be protected."

This statement is untrue! Major Gen. James C. Magee did not oppose the vaccinations. Had he done so, they would not have been made. There is no evidence that anybody is to be blamed for anything that should not have been done because there is no evidence that anything was done that was not warranted by the situation.

The *Tribune* persists in its reiteration that it was a mistake to vaccinate our troops against yellow fever—this in the face of the fact that inoculation against yellow fever is now a well established procedure, yielding immunity and protection against that vicious and fatal disease.

The report of the Army Medical Department also makes clear the difficulties of diagnosis of jaundice and of relating it definitely to the vaccination. The adviser or advisers of the editorial writer for the *Chicago Tribune* seems to be wholly unaware of the details associated with the entire procedure.

In its editorial statement the *Tribune* charges that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has misled its readers relative to this situation. That charge is untrue. The *Tribune* says

"When the facts were out and the *Tribune* had called for an impartial inquiry, he [the editor of THE JOURNAL] insisted that the Army was conducting a thorough investigation and that the report would be forthcoming promptly. He [the editor of THE JOURNAL] was wrong again."

The evidence of the untruth of this statement by the *Chicago Tribune* is apparent in the official report which is published in this issue of THE JOURNAL and which was sent to all medical officers of the United States Army. The statements of the *Tribune* relative to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION—which, incidentally, it carelessly calls the American Medical Journal—are just as unfounded as most of what the *Tribune* has printed relative to the entire situation.

FEDERAL AID FOR MATERNITY CARE FOR WIVES OF SERVICE MEN

Legislation has been introduced in the Congress, at the request of President Roosevelt, under which it is planned to provide maternity services for the wives of service men. The bill was introduced in the Senate as S. 2738 by Senator Barkley for Senator George and in the House as H. R. 7503 by Representative Doughton. It proposes to amend title V of the Social Security Act, relating to grants to states for maternal and child welfare, by adding the following provision:

Part 6—Wartime Services

Sec. 551. For the purpose of extending and improving services authorized in parts 1 [maternal and child health services], 2 [services for crippled children] and 3 [child welfare services] of this title by reason of conditions arising out of the present war, there are hereby authorized to be appropriated pursuant to sections 501, 511 and 521, and allotted pursuant to sections 502 (b), 512 (b) and 521, in addition to the sums specified in such sections, such sums as may be deemed necessary for each fiscal year during the period of the present war and six months following its termination. The chief of the Children's Bureau is hereby authorized to detail under emergency conditions arising out of the present war such personnel as may be necessary to cooperate with state agencies in carrying out the purposes of this title.

In transmitting this legislation to the Congress, President Roosevelt, after referring to the fact that the impact of war on family life has created urgent needs which previously authorized federal appropriations combined with state and local funds have not been able to meet, said, in part:

The legal basis for services for children contained in title V, parts 1, 2 and 3 of the Social Security Act, and the administrative foundations for such services developed in every state under the provisions of the act, are now available, but the funds authorized in this title are not sufficient to meet wartime needs. I recommend, therefore, an amendment which will authorize the appropriation of such additional sums as may be necessary to enable the Children's Bureau of the United States Department of Labor to cooperate with state agencies now administering maternal and child health services, services for crippled children and child welfare services in extending these programs to meet war conditions. It is estimated that the sum required for these purposes for the first year will not exceed \$7,500,000.

A draft of the proposed legislation is transmitted herewith. The provisions of the bill expire six months after the end of the present war, as is common with other wartime measures recently enacted by Congress. The draft bill maintains the normal procedure of allotting funds to the states provided by title V of the Social Security Act. However, all the additional sums authorized for maternal and child health services and services for crippled children are to be allotted in accordance with the provisions of sections 502 (b) and 512 (b), namely on the basis of the financial need of each state for assistance in carrying out its state plan for such services. To meet extraordinary wartime emergencies the bill also authorizes the chief of the Children's Bureau to detail such personnel as may be necessary to cooperate with state agencies in carrying out the provisions of title V.

Neither the President's letter transmitting the legislation nor the language of the bill itself discloses the detailed purposes for which this federal money will be spent. A release of the Office of War Information

(OWI-376), however, does contain information that reflects some of the major problems to be dealt with by the use of the funds to be made available. Katherine F. Lenroot, chief of the Children's Bureau of the United States Department of Labor, this release states, hails as a great wartime humanitarian move the President's request that Congress amend the Social Security Act to make more money available for child health and welfare services during the war period. She suggests that, of the total federal money to be made available, something over \$4,000,000 will be used for maternal and child health in war production areas, about \$750,000 for maternity care for wives of service men and about \$2,000,000 for the extension of child welfare services in overcrowded areas. The release leaves open the question as to whether maternity care will be supplied to the wives of defense workers to the same extent as it is proposed such care will be furnished to the wives of service men.

Miss Lenroot is quoted as saying:

I have long been deeply concerned over the serious effects of war on the well being of children in the United States. As early as the summer of 1940, reports began coming to the Children's Bureau of rapid increase in population in industrial areas to which war contracts were going and in military areas where encampments were being constructed. Overcrowded houses, trailer camps, lack of schools, lack of recreation facilities, too few public health nurses and doctors, and inadequate hospital facilities began to upset the opportunity for children to grow up into healthy, normal adults.

After Pearl Harbor these conditions were rapidly intensified and spread over large areas. Great numbers of children were also affected when their fathers left home for military or industrial service, and when the communities in which they lived began to feel the pinch of a shortage of such professional people as doctors, nurses and teachers.

Since December 1940 the advisory committees to the Children's Bureau have been recommending the provision of maternal and child health services and of child welfare services in defense communities and the increase of federal grants to the states for these purposes. The State and Territorial Health Officers in April 1941 and again in 1942 and the National Council of State Public Assistance and Welfare Administrators in December 1930 and again in 1941 made similar recommendations. Again and again these state administrators have written to the bureau describing the need for expanding maternal and child welfare services especially in the areas where increased population due to the war effort created great need for these programs. Special problems arose such as the need for hospital beds and medical care for maternity patients and sick children, the need for day care for children of working mothers and mounting juvenile delinquency.

So far as possible with the federal aid provided the state agencies made available health services for mothers and children and child welfare services in the areas where the need was most acute, but this could be done only to a limited extent.

The study given during the past two years as to the effect on children of defense preparations and war conditions has brought to light certain outstanding problems on ways and means for dealing with the problem, Miss Lenroot said. She listed these as (1) need for health services and medical care for mothers and children, especially in defense areas, (2) need for maternal care for wives of men in the armed forces and (3) need for child welfare services, especially in the defense areas, to assist in dealing with problems of child neglect

and juvenile delinquency. In addition to these major problems she declared there were many others affecting the well-being of children and said that federal grants to the states under the Social Security Act would give the states the urgent assistance they need in coping with these wartime conditions. This federal money, it is understood, will be allotted to the states on the basis of need and the money will not have to be matched in amount by state funds. In the Senate the bill has been referred to the Committee on Finance and in the House to the Committee on Ways and Means.

It is assumed that public hearings will be held to develop fully the facts concerning the necessity for this additional appropriation and the specific manner in which the program to be carried out under the bill will be administered.

"FOUND A ONE DAY CURE FOR SYPHILIS"

In the *Reader's Digest* for September appears an article by Paul de Kumpf entitled "Found A One Day Cure for Syphilis" heralded by the editors of that periodical as "the medical sensation of the year." In this article Mr. de Kumpf states that "now there actually is promise of a one day cure." He asserts without, of course, any basis in fact that "the standard eighteen month course of treatment is too painful, too dangerous, too prolonged for the mass cure of early syphilis." After describing certain experiments conducted by Drs. Walter M. Simpson, H. Worley Kendell and Donald L. Rose in the Miami Valley Hospital, he concludes:

With a one day cure available with plenty of doctors and nurses trained in fever therapy, and using equipment which costs little war material we ought really to begin to wipe out the horror of syphilis. There are a million active cases in the United States. With this powerful new treatment, all persons found infected with active syphilis could be taken out of circulation and their danger to the community quickly abolished. The immediate expansion of this chemothermic treatment should bring hope to those countless hundreds of thousands who are inadequately treated or who are not treated at all. In the meantime all those now under standard treatment should continue it until the new chemothermic treatment becomes generally available, thus for their own as well as for the public safety.

As nearly as can be determined all this effusion is based on a few paragraphs from an article on fever therapy by Drs. Walter M. Simpson, H. Worley Kendell and Donald Rose published in the *British Journal of Venereal Diseases* for January-April 1941, in which the authors state:

The present plan of treatment is as follows. A ten hour session of fever at 106 F. (41.1 C.) has been adopted tentatively as the initial unit of fever since these limits have proved to be safe and practical in the management of patients with refractory gonococcal infection. Prior to the fever session a single injection of 4 grains of insoluble bismuth is administered intramuscularly. During the first seven hours of the height of fever, 240 mg. of mapharsen are administered intravenously by the slow intravenous drip method. No additional antisyphilitic therapy is given.

To this they append the following highly conservative opinion

While no conclusions are permissible since the period of post therapy observation is as yet less than two years, the prompt resolution of clinical symptoms and the favorable serologic responses would indicate that further diligent inquiry is demanded. The results of this purely experimental undertaking will be made the subject of a later report

In their ultimate "conclusions" they say

At the present time such treatment should be considered strictly experimental

The results achieved thus far should stimulate other investigators to engage in long term, controlled experiments with a view to the introduction of a more rapid, more certain, less dangerous and less costly method of treatment

In a review of syphilis to appear soon in the *Archives of Internal Medicine*, Drs Frank W Reynolds, Charles F Mohr and Joseph Earle Moore of Baltimore say

With his usual uncritical judgment, hyperenthusiasm and willingness prematurely to capitalize journalistically on sober scientific experimentation, de Kruif has unhappily drawn nationwide attention to this "one day cure" for syphilis. This tendency of medical journalists to raise false hopes in lay minds can only be deplored. With all due respect to democratic freedom of speech, it is too bad that no censorship exists to compel conservative accuracy from medical sensationalists

This is another instance in which Mr de Kruif has expanded preliminary medical investigations into announcements to the public that go far beyond anything that the available evidence could warrant. THE JOURNAL is being deluged with letters from physicians indicating that the article already is doing great harm in creating dissatisfaction among persons with syphilis as to time that may be required to bring about cure. Dr Walter M Simpson is an officer in the Bureau of Medicine and Surgery of the United States Navy and has been for some months away from contact with the continental United States. It is unfortunate that in his absence the statements of Mr Paul de Kruif should have placed him and his research in such an unenviable position before the medical profession

THE USE OF BULK ETHER IN ANESTHESIA

Elsewhere in THE JOURNAL is a report¹ on the use of bulk ether in anesthesia, jointly sponsored by the Council on Pharmacy and Chemistry and the Committee on Drugs and Medical Supplies of the Division of Medical Sciences of the National Research Council. At the suggestion of the Committee on Drugs and Medical Supplies of the Division of Medical Sciences of the National Research Council, the Council on Pharmacy and Chemistry arranged for the preparation of this report

Apparently bulk ether has not been employed more widely for anesthesia mainly because of an impression regarding the possible deterioration of ether after it has been exposed to air. As far back as 1934 reports challenged the validity of the claim that ether should

be stored only in small containers, they have revealed also that ordinarily cans containing ether may be opened many times, if done carefully, without evidence when subjected to chemical tests for aldehydes and peroxides that the contents undergo deterioration. Other reports have discussed the technic of caring for bulk ether. One of these² presents in detail a satisfactory arrangement for a laboratory in which bulk ether may be handled. Included are descriptions of the lighting, ventilation, electrical switches and the specifications which have been set forth by the National Board of Fire Underwriters of New York on the question of handling ether in hospitals. Details, such as an appropriate sign on the door warning against smoking, and the value of records, are not forgotten. The author offers also a diagram of an apparatus used at his hospital to permit transferal of measured amounts of anesthetic ether from the bulk container to smaller cans.

The present report¹ substantiates others which claim that anesthetic ether can now be sold safely in large containers. The safety of storing is due largely to the chemical and pharmaceutical manufacturers, who by extensive research have been able to develop methods of manufacture which avoid the formation of peroxides. Originally peroxide formation was fairly rapid and dangerous. The experiments and experiences with the keeping quality of ether in bulk containers presented in the current report were made in large hospitals or moderately large hospitals in which the ether is used rapidly. Further, these hospitals have also the facilities to test the ether from time to time for the presence or absence of deterioration. In small hospitals, in which a bulk package of ether for anesthesia may amount to 30 pounds, it may not be utilized in six months or more, there is danger of its being peroxidized toward the end of that period. For such small hospitals the use of bulk ether would not be advisable.

The author of the report appearing in this issue of THE JOURNAL states that 'according to the new text (the Twelfth Revision of the U S Pharmacopeia) official ether for anesthesia may be stored in containers as large as 3 liters'. The Pharmacopeial statement reads "Ether to be used for anesthesia must be preserved in tight containers of not more than 3 Kg capacity". Three liters of ether would equal approximately 71 per cent of 3 Kg by weight and 3 Kg is equivalent to approximately 4,200 cc. In view of the restriction outlined in the Pharmacopeia it would be illegal to ship ether labeled "For anesthesia" in containers which contain more than 3 Kg. Actually, however, the editorial office of THE JOURNAL and the office of the Council on Pharmacy and Chemistry have been informed that ether which meets the standards of the U S P requirements is being shipped in drums which contain up to 30 pounds (13.6 Kg). Presumably such ether is not labeled "For anesthesia".

1 Gold Harry. The Use of Bulk Ether in Anesthesia. this issue p. 44

2 Clark-Donald A. Technic for Preparing Bulk Anesthetic Ether, American Professional Pharmacist February 1942

Superintendents and medical directors of hospitals can assume the responsibility of investigating the possible use of bulk ether in their institutions. The use of bulk ether, at least for the duration of the emergency, will be a contribution to conservation as a war effort. These are times when restrictions and savings bear special significance. Assuming that the evidence is now sufficient to permit the general use of bulk ether for anesthesia, provided the ether meets Pharmacopeial standards, there seems to be no reason why these official standards cannot be changed for the duration of the emergency so that the restricting statement "Ether to be used for anesthesia must be preserved in tight containers of not more than 3 Kg capacity" will not prove a legal bar to the general acceptance of bulk ether when indicated.

Current Comment

KANSAS ACCIDENT REPORT

The Kansas State Board of Health has issued its tenth consecutive report of accidental deaths occurring in the state.¹ Kansas was a pioneer state in the study and effective reporting of accidents as a cause of death. The report contains the usual statistical studies covering the state accidental death rate, which showed the highest number of accidental deaths since 1938, although this cause dropped from fifth to sixth place as the result of increases in other rates. As in other localities, the highest death rate from accidents is due to causes other than the automobile. These accidental deaths due to other causes are twice as numerous as those due to the automobile. The leading cause of death was drowning. Deaths among males were twice as great as among females. The largest number of accidents occurred in the age group between 80 and 84. Among the interesting features of this report has been the compilation of freak accidents. A 1 year old baby caught a navy bean in its larynx and choked to death. A boy enacting a scene from a book was strangled to death by a rope. A man riding on top of a load of trash was knocked off and killed when the truck drove into an underpass. A boy climbing a windmill to make adjustments was knocked to the ground when the wheel shifted with a change of wind. A 3 year old baby fell into a waste pit of a basement drain and was drowned. A man unfastened a chain which held a load of logs on his truck and the loosened logs slid and killed him. A mother trying to keep her child from falling out of an automobile fell from the car herself and was killed. A man fell into the greasing pit of a filling station, a young man was killed by a live wire while riding on top of a house in the process of being moved, inhaling furniture polish precipitated pneumonia in a small child. These and similar instances indicate the increasing importance of campaigns for safety. The report also presents suggestions for insuring safety in the home, with the motor vehicle, in the industrial situation and in the so-called public situation.

ADMISSIONS TO MEDICAL SCHOOLS

In an article by President Harry D Gideonse of Brooklyn College printed in the *New York Times*, August 9, the question is raised as to whether we are "gradually by deliberate organization and regulation trying to keep our own youth from making an effective transition to the economic responsibilities of adult life." President Gideonse refers to trade union rules, collective bargaining restrictions and other regulations designed to discourage newcomers in trades and professions. He cites the profession of medicine as an example of restrictive practices. Thus it is pointed out that the number of physicians and surgeons has declined from 160 per hundred thousand of our population in 1910 to 125 in 1930. The most reliable data available indicate that the number of physicians per hundred thousand of population in the United States did decrease from 146 in 1910 to 127 in 1930, but it had risen to 133 in 1940. With the increase in student enrolment and the adoption of an accelerated program of medical education, this proportion will rise still more rapidly within the next few years. The Commission on Medical Education, in its final report published in 1932, emphasized the low ratio of population per physician in the United States (780) as compared with European countries, which varied from 880 in Austria to 2,890 in Sweden. The commission in its report estimated that at that time there was an oversupply of at least 25,000 physicians in this country. The number of physicians actually needed and their most effective distribution are complicated problems involving most of the factors affecting our whole social organization. President Gideonse further states that "most New York educators know able youngsters who could not fail to meet objective standards and who find it hard, if not impossible, to enter training for their chosen profession." Inevitably in any system of higher education a considerable number, including many deserving and promising students are denied the opportunities which they seek. Few, if any, of the medical schools of the country are entirely satisfied with the quality and promise of all the students they admit to their schools. In spite of the most painstaking efforts on the part of admissions committees, many mistakes are made in the selection of students. This is shown by the large percentage of failures in the medical schools. Furthermore, the cost of medical education far exceeds that of any other type of higher education, and most of the medical schools of the country are now inadequately financed to meet their present responsibilities. From the point of view of sound education, financial support, personnel and the necessary physical and clinical facilities, it would be simply impossible to offer the opportunity of a medical education to every young American able to meet the specific subject requirements for admission to a medical school. Moreover, admission of some 12,000 to 14,000 who now apply instead of the 6,000 to 7,000 actually admitted would result in the production of great numbers of physicians who could never gain a livelihood or even find opportunity to work in the profession for which they had been educated. The effects on the standard of medical practice, the morals and the morale of the profession are easily imagined.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

THE OUTBREAK OF JAUNDICE IN THE ARMY

1 This Circular Letter, No 95, is issued as a supplement to Circular Letter No 45 S G O, dated May 13, 1942, Subject "Jaundice" For military reasons this report omits statements of numbers, rates and specific locations

2 (a) The occurrence of various types of jaundice among troops in the Army during January and February 1942 averaged about 125 cases a month Included among these were a few cases of the type of the disease which is the subject of this report Taking as a starting point the sudden appearance in widely separated locations of cases which were the first of a series of similar cases, the outbreak of jaundice in the Army may be said to have begun in the week ending March 7, 1942 The peak of the incidence among troops in the continental United States was reached in the week ending June 20, since when there has been a progressive and uninterrupted decline Advance, but incomplete, information from numerous stations indicates that there has been a further considerable decline in the past two weeks

(b) As jaundice of undetermined cause was not separately reportable on the statistical reports during March and early April it has been necessary to make extrapolations on the basis of samples to allocate portions of known totals to a few respective weeks These figures, as well as weekly figures, are being reviewed and revised frequently They are, however, nearly correct and it is not expected that final figures will make any significant change in the general graph of the outbreak

(c) Statistics for stations overseas, coming in more slowly, are less complete than those for stations in this country They indicate that the outbreak began in widely separated locations abroad at about the same time as the start of the outbreak in this country in the first two weeks in March The peak of incidence appears to have been reached a week or two later than in this country The decline is occurring progressively as in the continental United States The occurrence of cases at overseas locations, however, is particularly related to the arrival of certain troop units at their foreign destinations, and has varied in a manner similar to that of the fluctuating incidence of the disease in certain posts in this country

3 (a) The clinical course of the disease has been strikingly uniform in the great majority of patients It has resembled most closely the so-called "catarrhal

jaundice" or epidemic hepatitis of unknown etiology The onset is gradual, often imperceptible, until the appearance of jaundice Increased susceptibility to fatigue, lassitude and anorexia are the common prodromal or early symptoms, and in many cases are the only symptoms Nausea and vomiting may occur and diarrhea may precede other symptoms Fever is absent or the temperature may be slightly elevated The leukocyte count is usually normal, occasionally showing a relative increase of monocytes Pains in the joints and urticaria occur variably, usually in about 20 per cent of cases Darkly colored urine, yellowing of the skin and sclerae, and lightly colored stools are the rule The liver is found to be enlarged and tender in about 20 per cent of cases Bile pigments appear in the urine and blood The icteric indexes range from 15 to 200 occasionally to 300 Prothrombin levels are reduced and the results of excretion tests, such as the bromsulphalein test, indicate various degrees of disturbance of hepatic function Most often, cases have been mild, many discoverable only at special inspections In a smaller but considerable number the disease has been more severe showing a variety of stages of hepatic insufficiency The case fatality rate, based on reported admissions to hospitals, is approximately 0.2 per cent It would be considerably lower than this if the large number of cases treated in quarters or affected with only the milder and non-incapacitating symptoms were known and available for statistical computation The above brief outline has of necessity omitted description of many interesting and important clinical varieties of this disease, and has omitted also discussion of therapy Groups of investigators have been working on all phases of these subjects under the direction of the Surgeon General The reports of their findings will be published later

(b) In general recovery has followed in four to eight weeks As observations progressed a conservative tendency to prolong the convalescent period was widely manifested In some stations convalescent camps were established to permit continuation of supervision of diet and activities in a regimen by which the patient was returned to duty gradually Prognosis is favorable Sufficient evidence is available to warrant the statement that recovery is complete in the vast majority of cases and that permanent liver damage may occur in only a few

(c) A variety of diagnostic terms has been applied to this disease These have included "jaundice without

known cause," "catarrhal jaundice," "infectious hepatitis," "epidemic hepatitis," "cholangitis," "obstructive jaundice," "yellow jaundice" and, for reasons to be explained later, "postvaccinal hepatitis." In addition, the questionnaire in use and the blanket diagnosis employed have served as a dragnet for all types of jaundice. Furthermore, at this stage the statistics include records of cases originally diagnosed as "jaundice" but later found to be different. The process of sorting these out and making necessary corrections is in progress. The result will clarify the picture but will not alter the main characteristics of the outbreak.

4 (a) Pathologic material from all available sources has been assembled at the Army Medical Museum, Washington, D. C., which has in effect established a central registry for specimens from cases of this disease. Comparative studies are being conducted on an extensive scale. It is requested that gross material from fatal cases of hepatitis, together with copies of the clinical abstracts, immunization records and autopsy protocols be sent promptly to the Army Medical Museum. Of special importance is material which may be used in studies to determine the nature and extent of any late effects of the disease. Officers performing post-mortem examinations on persons who have died from accident or disease are requested to state, when possible, in the protocol whether the deceased has suffered from an attack of jaundice, within a period of one year or longer prior to the date of autopsy. This request is made in order to gather further information concerning the repair of liver injury.

(b) The chief pathologic lesions are those of acute or subacute yellow or red atrophy of the liver. The earliest lesions consist of frank necrosis of liver cells in the central parts of the lobules. There are no inclusion bodies present at any stage. The lesions differ distinctly from the lesions of yellow fever.

(1) In the fatal cases of hepatitis observed during the present year, death usually has occurred from two to six weeks after the onset of the disease. The earlier stages of hepatitis have rarely been observed. It is evident that the destructive process and the removal of debris by lysis is rapid. Within ten days the bulk of the necrotic material has usually been removed completely. The stroma is rarely damaged to any extent, in many areas the lobular framework remains intact. In most cases the destructive process is not diffuse, the severity of the damage tends to vary in different parts of the liver. In some areas the hepatic tissue is almost completely destroyed, whereas in other areas only the central parts of the lobules become necrotic. Unlike many forms of destructive liver disease, fatty changes are not a conspicuous feature in hepatitis of the type here discussed. Repair of the injured liver is brought about mainly by multiplication and hypertrophy of remaining liver cells. The resulting lobules tend to be very large but are often of atypical construction. The part played by "regenerated bile ducts" and the origin of these tubular structures is controversial. Destruction of liver tissue and the removal of debris is in this disease invariably accompanied by inflammatory reaction and, hence, the term "hepatitis" is proper.

(2) Changes in organs other than liver are common. Of particular interest is the marked edema, often accompanied by intense inflammation of the gastrointestinal tract. Although any part of the tract may be involved,

including the esophagus, the changes are usually most pronounced in the cecum. The relation of these lesions to the hepatitis is not as yet known. The kidneys may present the picture commonly known as bile nephrosis (cholemic nephrosis). An acute or subacute splenic tumor is usually present. Hemorrhages, often extensive, in serous and mucous membranes are likewise common. The central nervous system often shows changes similar to those found in other severe toxic metabolic disturbances.

(3) To what extent is the liver damaged in the average nonfatal case of hepatitis? To what extent is this damage repaired? These questions are of great interest. It must be emphasized that the extensive damage observed in the rare fatal cases are not duplicated in the nonfatal cases. It is more than probable that "yellow or red atrophy" represents the extreme end of a scale of lesions on which there are many gradations from the usual slight and readily repairable injury such as occurs in the average patient, to the extensive destruction of tissue in the fatal case. In livers from patients who have died from accident or disease subsequent to an attack of jaundice, little or no evidence of preceding damage has been found. All information available at present indicates that in the average patient hepatic damage is slight, and repair prompt and complete.

5 (a) Etiologic investigations, started in March, have been carried on in many laboratories in the Army and in laboratories of several universities and research institutes at the home stations of members of the Board and Commissions, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army. Although the outcome of some experimental inoculations made about four months ago seems to offer promise that the jaundice-producing agent may be discovered ultimately, the results to date have been negative as far as the demonstration of a transmissible agent is concerned. These negative results, however, have served to exclude a number of infectious diseases in which jaundice occurs. The outbreak of jaundice in the Army is not Weil's disease or any type of leptospiral infection. It is not a bacterial infection and has no relation to infectious mononucleosis. The disease is not yellow fever nor a modified form of yellow fever. Yellow fever virus has not been recovered from any material (blood, bile, urine, liver, etc.) from jaundice patients.

(b) The search for the icterogenic agent or factors producing this type of jaundice is progressing along two main lines. One of these is an attempt to transmit the disease with materials derived from patients. The other is an attempt to reproduce this type of jaundice in animals with yellow fever vaccine or its compounds. Experiments are being conducted with the whole vaccine using lot numbers known to have been associated with a high incidence of jaundice, and as control lots not associated with jaundice. On the assumption that the component of human serum in certain lots of vaccine administered up to April 18, 1942 may have carried an icterogenic agent, the donor lists are being analyzed and experimental inoculations may be made with the blood of some individuals who contributed pools of serum. Probably it will be impossible directly to attack the question as to whether the chick embryo component carried the icterogenic agent. Immunologic factors

involving the operation of an organ-specific (liver) antigen-antibody system are also being investigated

(c) The serum of patients with jaundice occurring several weeks or longer after vaccination against yellow fever contains antibodies capable of neutralizing yellow fever virus. It is known from tests that jaundice has occurred in persons immune to yellow fever. On the other hand the serum of a jaundice patient who has not been injected with yellow fever vaccine does not possess these virus-neutralizing properties. These immunologic studies strengthen the conviction that another agent than yellow fever virus is the cause of the jaundice or that another process than the contact of the vaccine virus with cells is the cause of the pathologic changes in the liver.

6 (a) Epidemiologic investigations have been carried out to a greater or less extent at almost every location in this country and overseas, at which an outbreak of jaundice has occurred. A mass of data in the forms of individual questionnaires and detailed studies of jaundice in troop units and at posts, camps and hospitals has been assembled at this office. With the exclusion of leptospiral and bacterial causes of jaundice the epidemiologic study has dealt chiefly with the question: Is this outbreak an epidemic of infectious hepatitis (so-called catarrhal jaundice) or is it a non-contagious hepatitis following administration of yellow fever vaccine?

(b) Epidemics of hepatitis and jaundice with clinical and pathologic manifestations similar to the outbreak now ending have occurred among troops in the armies of many nations in the past. During the first year of the Civil War there were 10,929 reported cases with 40 deaths among Northern troops. The French have referred to the disease as the "Jaundice of Camps" and the English have often called it the "Jaundice of Campaigns." There were 2,195 cases of epidemic hepatitis in British troops in the Mesopotamian-Dardanelles region from Sept 5 to Nov 6, 1915. It is a common enough disease of armies and camps and of groups of young adults in civilian institutions. Recently this office has received reports of the occurrence of jaundice in British and German troops in Africa and in troops of the United Nations in the Middle East and in India. Outbreaks of jaundice in civilian communities in this country and abroad have been well described in the past and are also subjects of recent reports. That jaundice of the usual so-called catarrhal type may have occurred and may be occurring among troops of the United States Army in certain locations is unquestionable. Outbreaks of such cases among troops and civilians are characterized by an incubation period of twenty to thirty-five days or less and a spread by contact. As stated above, the number of cases of jaundice of this type in the Army appears to have been about 125 per month in the first two months of this year. No extensive outbreak of jaundice in the civil population has occurred in this country in the past year.

(c) The incidence of cases of hepatitis and jaundice in the present outbreak in the Army has shown the following special features:

(1) Simultaneous occurrence in troops in locations widely separated, from the Pacific to the Atlantic and from the North to the South, with notable intermediate locations.

(2) Absence of demonstrable contacts between these units.

(3) Invariable association of all large outbreaks and many small outbreaks with administration of certain lots of yellow fever vaccine.

(4) The predictable occurrence of cases of jaundice in groups of individuals, troop units and others known to have received these lots of vaccine.

(5) The predictable occurrence of a certain percentage of cases of jaundice at stations to which troops known to have received certain lots of vaccine were dispatched.

(6) The occurrence of a certain percentage of cases of hepatitis and jaundice after an incubation period of seventy to ninety days following administration of the above mentioned lots of vaccine. This incubation period has extended from about forty to one hundred and twenty days, depending on lot numbers and conditions to which the individual was exposed. A few cases may occur as long as six months after vaccination.

(7) The occurrence of large numbers of cases of jaundice in large groups of individuals vaccinated with one or the other of these lots and the occurrence of a few cases in instances in which subdivisions of the groups received these lots while the more numerous group of "contacts" free from jaundice received other lots of vaccine or were not vaccinated against yellow fever.

(8) The absence, to date, of secondary outbreaks in locations at which this type of jaundice has occurred. This has been true of places in which there were large numbers of cases following yellow fever vaccination and in places in which the patients of postvaccinal jaundice were in the midst of many times their number of nonvaccinated individuals or individuals vaccinated with nonicterogenic lots.

(9) Examples could be multiplied. They are the basis for the conclusion that this outbreak is a type of jaundice following the administration of certain lots of yellow fever vaccine and that the disease is not contagious and hence does not constitute a danger to the public health.

(a) When it appeared likely that the jaundice was associated with vaccination against yellow fever, the Surgeon General, early in the spring, ordered discontinuation of the vaccine then in use until problems were satisfactorily solved and a change to another source of vaccine. Since then the vaccine has been prepared without the human serum component. It is believed the risk of jaundice has been eliminated. The distribution of vaccine was limited to ports of embarkation and the Air Surgeon. Later, vaccination of troops against yellow fever was limited temporarily to military personnel traveling to or through or stationed in areas in which yellow fever is endemic. As defined by the Surgeon General, after consultation with specially informed authorities, these areas are in the Western Hemisphere, the mainland of South America lying between latitudes 13 degrees north and 30 degrees south, including the islands immediately adjacent, in the Eastern Hemisphere, the portion of Africa lying between latitudes 16 degrees north and 12 degrees south, including the islands immediately adjacent.

(b) Regulations concerning vaccination against yellow fever are matters of international importance. Those in effect for the United States Army are coordinated with British regulations applicable to areas in which yellow fever is endemic or a potential hazard.

OPHTHALMIC SURGERY IN THE RUSSIAN ARMY

VLADIMIR FILATOV

Member Academy of Sciences U S S R

NOTE—*The following message and paper were radioed to THE JOURNAL from Moscow. Most of the methods discussed have been previously published. The article is printed here primarily because of the unusual circumstances associated with it*—Ed

SU—*With a view to establishing close cooperation in our struggle against Hitlerism, we send you an article by Academician Vladimir Filatov with the request that you publish it in THE JOURNAL, which is greatly respected by medical circles of America and Europe.*

There is no doubt that cooperation of Russian and American scientists will contribute to victory.

ACADEMICIAN DERZHAVIN,
President, Soviet of Antifascist Scientists

ACADEMICIAN PILIPCHUK,
Secretary

The vicissitudes of war have brought us from Odessa to Tashkent, where excellent conditions have been procured by the Soviet government to promote our researches. I shall mention here only the principal achievements of my school, which may prove useful for treating wounded and sick soldiers in our heroic army.

PLASTIC SURGERY BY THE ROUNDSTALK METHOD

First is my new method of plastic surgical operation by the so-called roundstalk method first described in April 1917. A similar method was suggested somewhat later by Gillies. The main essentials are as follows.

A wide band is cut from the patient's skin two or three weeks prior to surgical intervention in which it is anticipated that the existence of scars or tumors may result in the formation of some defect. Its ends are preserved intact and the margins are stitched together so that it assumes the shape of a cylindric structure or "stalk." In the course of the plastic operation one end of the stalk is cut off together with the skin fragment the latter being grafted as a leaf on a stalk to the defect, to which it is sewn. After ten days the stalk is cut off the fragment and the operation is completed by sewing it definitely. The advantage of the round stalk method over previous methods of plastic operations is that it is fairly large, owing to the development of blood vessels, thereby securing proper nutrition of the fragment and it is protected from infection. The round stalk may be prepared far off from the site of the proposed plastic operation. It is made to approach the defect with one or another end being alternately sewn up every fortnight to skin cuts made along its path. The round stalk method has been epoch making in plastic surgery and is widely applied especially in wartime for restoration of lost or mutilated parts of the body (such as the nose, eyelids, lips, cheeks and fingers). The twenty-fifth anniversary of this method was recently celebrated by Soviet surgeons. I have dedicated this method to our heroic Red Army.

TRANSPLANTATION OF CORNEA

The second achievement of my school applied in military surgery is transplantation of the cornea to cure blindness or invalidity resulting from persistent opacity of the cornea, so-called wall eye. The latter is

caused by corneal infections (by ulcerations) as well as by trauma and burns, either chemical or thermal.

The old method and technique of corneal transplantation have been essentially improved. By means of special instruments and trephines some dangerous complications of operations, including injury to the lens, can be avoided. It was shown that the cornea of cadavers' eyes kept one to three days at low temperature (a few degrees above zero) heals better in the patient's "wall eye" than that from a live donor. Thus copious source material for corneal transplantations has been discovered, the number of operations amounting now to about one thousand. Thanks to support of our government, this beneficent operation is now widely applied by Soviet ophthalmologists.

I have had the pleasure of demonstrating my methods of corneal transplantation as well as patients to our American guest physicians and former United States Ambassador Steinhardt, also to a group of English surgeons, among whom I may mention the notable Edinburgh ophthalmologist Professor Ingham, who has also attended my operations.

TRANSPLANTATION OF TISSUE AS STIMULATOR
OF BIOCHEMICAL PROCESSES

The third achievement which my school has introduced into surgical wartime practice is therapeutic application of surviving tissues of both man and animals.

I have succeeded in showing that corneal transplantation may be used not only for optic purposes but also to cure corneal infections. Particularly effective in this respect is transplantation of cadavers' corneas preserved at low temperature (three degrees above zero). For this purpose a fragment of cornea is grafted to an incomplete defect made at the margin of the patient's cornea. Further inquiry showed that almost every kind of human tissues preserved six to seven days at low temperature will exert powerful curative action. Tissues may be derived from another person (and from the cadaver) as well as from the patient himself. Animal tissues are also effective as well as some body fluids, such as aqueous humor or cerebrospinal fluid, provided they are derived from preserved cadaver or from preserved tissues and organs. For preference I use preserved skin (transplanted to a cut made in the patient's skin) as well as implantation of preserved placenta, grafting of mucosa, injection of aqueous humor from a preserved bovine eye or extracts from preserved tissues.

This method gives remarkable results in treating a number of diseases, both ocular and nonocular. Thus it has been successfully applied in tuberculosis (of the skin, throat and lungs), in treating various kinds of ulcers (particularly obstinate wounds), scars (particularly scar contractures of soldiers), lesions of the peripheral nervous system (particularly of traumatic origin), skin diseases, gynecologic disorders, arthritis and allergic diseases (bronchial asthma). Of ocular diseases I may mention corneal inflammation (tuberculosis and trachoma), infections of the choroid and retina such as chorioretinitis of the shortsighted, pigment retinitis and atrophy of the optic nerve. This

method has been tested during many years and is now widely applied for treating wounded and sick soldiers of the Red Army

The theoretical principles underlying this method are that Vital functions of isolated tissue kept at low temperature are preserved. This is possible only on condition that tissue undergoes some reconstruction resulting in formation of certain stimulants (accelerators) of biochemical processing going on within the organism. Stimulants (which I call "preservation factors") of tissue or tissue fluids stimulate metabo-

lism of recipient's cells thereby enhancing regeneration processes in the wide sense of this term

It is of course my duty as a citizen enthusiastic, together with all Soviet people, to free my country from invasion of the enemy to introduce achievements of my school into the practice of military hospitals. This is why I deem it necessary, apart from my personal surgical obligation, to discuss the methods of our school in reports made to civil and military surgeons of Tashkent and to submit them to the attention of my American colleagues

STANDARDS FOR MATERNITY CARE AND EMPLOYMENT OF MOTHERS IN INDUSTRY

PREPARED BY THE CHILDREN'S BUREAU AND THE WOMEN'S BUREAU OF THE
U S DEPARTMENT OF LABOR IN CONSULTATION WITH

MRS DOROTHY J BELLANCA, Amalgamated Clothing Workers of America, New York

MISS ELIZABETH NORD, Textile Workers Union of America, Providence, R I

MISS ROSE SCHNEIDERMAN, New York State Department of Labor, New York

DR H CLOSE HESSELTINE, Department of Obstetrics and Gynecology, University of Chicago School of Medicine, Chicago

DR N J EASTMAN, Department of Obstetrics, Johns Hopkins University School of Medicine, Baltimore

DR JAMES G TOWNSEND, Division of Industrial Hygiene, National Institute of Health, Bethesda, Md

MISS ELEANOR RANTOUL, Industrial Hygiene Bureau, Metropolitan Life Insurance Company, New York

GENERAL STATEMENT

With increased employment of women in industry, the problem of protection of the pregnant woman and her child has become more urgent. Many inquiries have come to the Women's Bureau and to the Children's Bureau from a variety of sources, such as employers, workers and health departments, concerning the types of work suitable for pregnant women and the policy of maternity leave. The labor situation in this country does not necessitate the recruitment or employment of pregnant women or women with infants. A woman who is expecting a child should give first consideration to her own health and to plans for safeguarding the health and care of the child. Because some women who are pregnant or who have young children may find it necessary to work, the following statement of policy has been formulated to serve as a working basis for those concerned with this problem. It is recognized as a general policy that provisions for maternity care and leave should not jeopardize the woman's job or her seniority privileges.

EMPLOYMENT POLICIES AND CARE FOR PREGNANT WOMEN

These recommendations are based on the premise that, to safeguard the pregnant woman who works, certain special provisions should be made. She should have opportunity for adequate antepartum care. She needs sufficient time off before delivery to allow her to be in a rested state at the time of delivery and to prevent undue strain in the latter part of pregnancy. If she is employed in certain occupations that involve hazards or strain, or if complications of pregnancy occur she needs special consideration. It is not possible to lay down hard and fast rules that will fit every situation. The wide variation in general physical condition and in the amount of home duties performed outside working hours necessitates some individualization of arrangements for maternity leave and protection.

The following general recommendations are made as a guide:

1 Facilities for adequate antepartum medical care should be readily available for all employed pregnant women, and arrangements should be made by those responsible for providing antepartum care so that every woman will have access to such care. Local health

departments should make available to industrial plants the services of antepartum clinics, and the personnel management or physicians and nurses within the plant should make available to employees information about the importance of such services and where they can be obtained.

2 Pregnant women should not be employed on a shift including the hours between 12 midnight and 6 a m. Pregnant women should not be employed more than eight hours a day or more than forty-eight hours a week, and it is desirable that their hours of work be limited to not more than forty hours a week.

3 Every woman, especially a pregnant woman, should have at least two ten minute rest periods during her work shift, for which adequate facilities for resting and an opportunity for securing nourishing food should be provided.

4 It is not considered desirable for pregnant women to be employed in the following types of occupation, and they should if possible, be transferred to lighter and more sedentary work.

(a) Occupations that involve heavy lifting or other heavy work.

(b) Occupations involving continuous standing and moving about.

5 Pregnant women should not be employed in the following types of work during any period of pregnancy but should be transferred to less hazardous types of work.

(a) Occupations that require a good sense of bodily balance, such as work performed on scaffolds or step ladders, and occupations in which the accident risk is characterized by accidents causing severe injury, such as operation of punch presses, power driven woodworking machines or other machines having a point of operation hazard.

(b) Occupations involving exposure to toxic substances considered to be extra hazardous during pregnancy, such as

Aniline	Nitrobenzene and other nitro compounds of benzene and its homologues
Benzene and toluene	Phosphorus
Carbon disulfide	Radioactive substances and x rays
Carbon monoxide	Turpentine
Chlorinated hydrocarbons	
Lead and its compounds	
Mercury and its compounds	

Other toxic substances that exert an injurious effect on the blood forming organs, the liver or the kidneys.

Because these substances may exert a harmful influence on the course of pregnancy, may lead to its premature termination or may injure the fetus, the maintenance of air concentrations within the so called

maximum permissible limits of state codes is not, in itself, sufficient assurance of a safe working condition for the pregnant woman. Pregnant women should be transferred from workrooms in which any of these substances are used or produced in any significant quantity.

6 A minimum of six weeks' leave before delivery should be granted on presentation of a medical certificate of the expected date of confinement.

7 At any time during pregnancy a woman should be granted a reasonable amount of additional leave on presentation of a certificate from the attending physician to the effect that complications of pregnancy have made continuing employment prejudicial to her health or to the health of the child.

EMPLOYMENT POLICIES AND CARE FOR THE MOTHER AND INFANT AFTER DELIVERY

To safeguard the mother's health she should be granted sufficient time off after delivery to return to normal and to regain her strength. The infant needs her care, especially during the first year of life. If it is essential that she return to work, the following recommendations are made:

1 All women should be granted an extension of at least two months' leave of absence after delivery.

2 Should complications of delivery or of the postpartum period develop, a woman should be granted a reasonable amount of additional leave beyond two months following delivery, on presentation of a certificate to this effect from the attending physician.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

1 MEMORANDUM FOR ADMINISTRATORS OF HOSPITALS APPROVED FOR INTERNSHIPS AND/OR RESIDENCIES

The directing board of the Procurement and Assignment Service has addressed the following memorandum to the administrators of all hospitals approved for internships and/or residencies:

The directing board has appointed the following hospital administrators to serve on an advisory Committee on Hospitals: Dr M T MacEachern, associate director American College of Surgeons, Chicago, chairman, Dr Claude W Munger, director, St Luke's Hospital New York, Dr Benjamin W Black, medical director Alameda County Institutions and superintendent, Alameda County Hospital, California, Dr Lucius Roy Wilson, superintendent, Hospital of Protestant Episcopal Church, Philadelphia, and Dr Basil C MacLennan, director, Strong Memorial Hospital, Rochester, N Y, and president, American Hospital Association.

This committee has recommended, and the directing board has approved, the following procedures and criteria to be used in preparing the revised lists of essential hospital staff members.

The many changes which have occurred in appointments of hospital interns and residents on or about July 1 and the urgent need of the armed forces for young medical officers make necessary at this time a revision of the lists of essential personnel on hospital staffs. Believing that you will prefer to make voluntary reductions in your staff we ask for your fullest cooperation in our effort to assist you in maintaining your minimum essential staff.

Each hospital administrator has a definite responsibility to provide the necessary medical services for the patients of his hospital. In many hospitals, particularly those which care for charity patients and which are affiliated with medical schools, the retention of a minimum resident staff is essential both for the care of the patients and for medical education. Nevertheless it is obvious that drastic reductions in the peacetime staffs of hospitals must be made if the needs of the armed forces are to be met.

Analysis of the original lists of essential personnel in hospitals indicates that in many institutions further reductions can and should be made. In preparing these lists the attitude should be not 'How many can we possibly retain?' but 'How many can we possibly release for service with the armed forces?'

1 In compiling lists consider only full time staff members, part time staff members conducting essential hospital services (e.g. roentgenologist), visiting staff members who actually conduct ward work, residents and interns.

(a) Residents should be considered essential on the basis of general hospital work and not because of the service they render in the care of private patients, except as it contributes to their training.

(b) Individuals who have completed one year of internship shall be considered available for military service unless they are appointed to an essential position as a hospital resident.

2 Do not consider visiting or courtesy staff members who serve only private patients. Their essentiality will be determined by the local Procurement and Assignment committees on the basis of their services to the community as a whole rather than their need in any particular hospital.

3 The residency program must be drastically curtailed and the number of residents decreased in numbers.

4 Subsequent to July 1, 1942 and during the war emergency, designation of a man as an essential hospital resident or fellow should not exceed two years beyond the completion of one year's internship.

5 Having determined the minimum number of essential positions, these positions should be filled as far as possible by:

(a) Women

(b) Young men physically ineligible for military duty and older men.

6 Visiting staff members should be asked to contribute additional hours to their duties in the hospital.

7 Routine work of residents and interns should be delegated as much as possible to qualified nonmedical personnel for clerical, laboratory and other services.

8 One copy of the revised hospital list should be sent to the state chairman of the Procurement and Assignment Service and one copy to this office within one week of the receipt of this letter. A sample form for this report is enclosed.

9 It is important that every hospital staff member be informed by the hospital as to classification as essential or available subject to approval by the Procurement and Assignment Service.

10 Your continued cooperation in this effort on the part of the Procurement and Assignment Service to provide medical personnel for the armed forces and at the same time to maintain essential hospital services during the war will be appreciated.

A blank is provided on which hospital administrators are requested to furnish full information regarding all staff members.

2 CRITERIA FOR DETERMINATION OF ESSENTIAL PHYSICIANS IN INDUSTRIAL MEDICINE

The situation regarding recruitment of physicians now employed in industrial medicine has caused the directing board of the Procurement and Assignment Service to send the following memorandum to all state chairmen relative to the methods by which the essentiality of physicians engaged in industrial medicine may be determined.

A serious situation is developing in some states because physicians under 45 years of age who are essential in their present positions as key men in industrial practice are being declared available by state chaimen or are being approached directly by recruiting boards with instructions to apply for a commission in the Army Medical Corps.

The Selective Service System and the Surgeon Generals of the Army and of the Navy are cooperating with us to keep at their posts the physicians declared to be essential by our state committees. In determining essentiality, please be guided by the following criteria, which have been recommended by the Committee on Industrial Health and Medicine and have been approved by the directing board.

In some instances an industrial physician under 37 years of age will be deemed essential according to these criteria, and yet you may think he should be made available. In this case it is your responsibility to obtain a replacement and to notify the central office at once when the industrial physician will be available.

A physician employed in industry is deemed to be essential when the following conditions exist:

A Full time industrial physician

1 The physician is employed by an industry which is manufacturing war materials exclusively or under priority ratings, and

2 The physician gives his full time to the industry or forty or more hours weekly, has been so employed for at least two years, or is especially trained for that purpose and is carrying on an acceptable health maintenance program and

3 The physician is performing the function of a medical director or department head or of a specialist or is the only physician employed.

4 Assistant physicians who perform routine functions under direction and are employed on a full time basis are deemed essential until they can be replaced within a reasonable time (three to six months).

B Part time industrial physician

1 The physician serves part time two or more industries engaged exclusively in the manufacture of war materials or under priority ratings, provided his total part time service is the equivalent of forty or more hours weekly. Note: The physician who serves on call only is not deemed to be essential.

C The physician serves a state industrial hygiene bureau on a full time basis.

ORGANIZATION OF EMERGENCY BASE HOSPITALS

The following statement from the Surgeon General, U S Public Health Service, has just been sent to a selected group of medical schools and hospitals:

Selected hospitals and medical schools in the coastal states have been invited by the Surgeon General of the U S Public Health Service to organize affiliated staff units which will be ready to serve when needed to supplement the medical staffs of emergency base hospitals now being designated by the Medical Division of the Office of Civilian Defense.

These units resemble the affiliated hospital units of the Army, except that they are smaller. They are being organized in order to assure suitable status and remuneration for physicians who may be called on in the event of an enemy attack in their locality to care for casualties and other patients who have been evacuated to the interior of their region.

The designation of emergency base hospitals and the formation of affiliated units are part of a joint hospital program of the Medical Division of the Office of Civilian Defense and the U S Public Health Service. The program is authorized under an agreement concluded March 2, 1942 between the Federal Security Administrator and the director of the Office of Civilian Defense.

Physicians in the affiliated units will be commissioned in the inactive Reserve Corps of the Public Health Service. Unless an urgent need for their services should arise, they will remain on an inactive status for the duration of the war. They will be called to active service only if hospitals in their regions must be evacuated and the civilian populations must be moved because of military necessity. Activation of the units will take place by order of the Surgeon General at the request of the chief medical officer of the Office of Civilian Defense on advice of the regional medical officer and the state chief of Emergency Medical Service in charge of the affected areas.

The commissions will be in grades ranging from Passed Assistant Surgeon to Senior Surgeon and when units are activated these officers will have the rank, pay and allowances equivalent to those of officers in the armed forces. The accompanying table of organization shows the composition of the unit.

Institutions invited to form units are asked to nominate an outstanding physician or surgeon as unit director who if he meets the physical and other requirements, will be commissioned Senior Surgeon in the Public Health Service Reserve. The unit director will then nominate the remainder of the staff and appointments will be made after clearance through the state chief of Emergency Medical Service. Nominations are to be limited to male physicians over 45 years of age to those under that age who have physical disabilities which disqualify them

for military service, but which do not interfere with their professional activities and to women physicians.

In order to avoid serious depletion of the professional staffs in the medical schools and hospitals of the target areas the

Organization for U S Public Health Service Office of Civilian Defense Affiliated Units

Number Required	Position in Unit	USPHS Title	Equivalent Army Rank
1	Chief of medical services	Senior Surgeon *	Lieutenant Colonel
1	Assistant chief of medical services	Surgeon	Major
2	General internists	Passed Assistant Surgeon or Surgeon	Captain or Major
1	Chief of surgical services	Senior Surgeon *	Lieutenant Colonel
1	Assistant chief of surgical services	Surgeon	Major
2	General surgeons †	Surgeon	Major
2	General surgeons †	Passed Assistant Surgeon or Surgeon	Captain or Major
1	Orthopedic surgeon	Surgeon	Major
1	Assistant orthopedic surgeon	Passed Assistant Surgeon or Surgeon	Captain or Major
1	Dental surgeon	Passed Assistant Surgeon or Surgeon	Captain or Major
1	Pathologist	Passed Assistant Surgeon or Surgeon	Captain or Major
1	Radiologist	Passed Assistant Surgeon or Surgeon	Captain or Major
—			
15			

* One of the two senior surgeons will be the unit director.
† In place of one or more of the general surgeons a urologic surgeon, thoracic surgeon, neurosurgeon or plastic surgeon may be included.

Surgeon General has recommended that medical schools draw their affiliated units in part from associated hospitals and that nonteaching hospitals invite physicians from other qualified hospital staffs to collaborate.

DR ROY HALLORAN ON DUTY IN SURGEON GENERAL'S OFFICE

Dr Roy D Halloran, superintendent Metropolitan State Hospital, Waltham, Mass., has been commissioned lieutenant colonel in the U S Army and assigned to duty as consultant in neuropsychiatry in the Surgeon General's Office, Washington, D C. Dr Halloran, who assumed his new duties on August 17, will coordinate the neuropsychiatric service in the army both in this country and overseas. He was born in Massachusetts in 1894 and graduated from Columbia University College of Physicians and Surgeons in 1920. He has developed postgraduate courses in psychiatry and neurology, engaged in research and in 1935 organized the Child Guidance Clinic in Waltham.

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status—S 2676 has passed the Senate, to provide for medical care and funeral expenses for certain members of the Naval Reserve Officers' Training Corps

Bills Introduced—S 2726, introduced by Senator Clark, Missouri, proposes to make available to veterans of the present war the medical and hospitalization benefits now accorded to veterans of World War No 1 S 2738 introduced by Senator Barkley, Kentucky, for Senator George Georgia and H R 7503, introduced by Representative Doughton North Carolina, propose to amend Title V of the Social Security Act relating to grants to states for maternal and child welfare so as to authorize such additional sums as may be necessary to extend and improve services for maternal and child health, for crippled children and for child welfare The President in submitting this legislation to Congress, indicated that an additional appro-

pration of \$7 500,000 would be required for the first year to carry out the purposes of the bill The bill, if enacted, will be in effect for the duration of the present war and for a period of six months thereafter The Acting Administrator of the Federal Security Agency has transmitted to the Congress a draft of proposed legislation to reorganize and redefine the duties of the United States Public Health Service

DISTRICT OF COLUMBIA

Bill Introduced—H R 7506, introduced by Representative Randolph, West Virginia, proposes to amend the law relating to registration of births in the District of Columbia by providing, among other things, for the delayed registration of a birth, for the issuance of a certificate of birth where a child of unknown parentage is adopted and for the issuance of a birth certificate in case the paternity of a child is unknown

MEDICAL ECONOMIC ABSTRACTS

TUBERCULOSIS ON THE WAY OUT?

A mortality summary for the U S registration states on tuberculosis of the respiratory system issued by the Bureau of the Census, July 17, lends considerable encouragement to those who believe that, within a now appreciable time, tuberculosis will join a number of other destructive plagues as of interest only to medical historians The registration area was not completed until 1933 The states added between 1900 and 1933 were often among those having the highest mortality rates yet since 1900 the tuberculosis mortality rate has fallen from 174.5 per hundred thousand of population to 42.2 This means a reduction of a little over 75 per cent during this century

Since 1933, when the registration area first included the entire United States, in spite of the increase in population the decline in the absolute number of deaths from tuberculosis has been continuous, from 67,422 deaths in 1933 to 55,576 in 1940

Further encouragement is offered by the fact that in certain states and in some whole sections of the country the present death rate is very much lower than the average for the whole United States In the entire West North Central division embracing seven states, the rate in 1940 was 26.3 There are fourteen states in which less than 30 out of every 100,000 died from tuberculosis of the respiratory system in the latter year The decline has been continuous for all ages and both sexes, and, while the rate for Negroes is still almost three times as high as for white persons, the rate of decline has in recent years been about the same for the two races The expansion of institutional care is shown by the fact that only 44 per cent of the deaths in 1940 took place outside some institutions

ADDITIONAL AMERICAN FIGHTERS

Better health care has added a powerful force of 2,800,000 men, equal in number to the entire United States draft army of 1917-1918, and double the number of those who saw service in France, to the military and productive strength of the nation, according to the statisticians of the Metropolitan Life Insurance Company

About 11 per cent of the 25,800,000 men at present in the draft ages 20 to 44 would not be living if mortality conditions of 1900 had prevailed until the present time In fact, some of the men now living would never have been born, because their parents would have been among the victims of the higher mortality as of 1900

The statisticians say "What is perhaps not generally realized is that a very considerable part of our fighting force and industrial productive force is the direct result of reduced mortality

since the beginning of the century, and this in turn is to be credited to our organized public health effort and the remarkable advances of medical science in those decades"

NURSES WANTED FOR WAR

The 1942 census in the United States reported 369,287 "trained nurses in the United States A national inventory of registered nurses in 1941 found that 173,055 were actively engaged in nursing practice Nurses are eligible for military duty only if they are under 40 years of age and unmarried and only 89,327 met this requirement To this, however, must be added 9,366 who were qualified but were not in active nursing work This would give approximately 100,000 eligible for military duty

Nursing schools reported an increased enrolment in 1942 of approximately 8,000 students The nurses are determined to meet the war situation without lowering standards, preparation and service Some of the ways suggested at the state board conference held immediately following the biennial conference of the nursing association were that students' vacations be cut or eliminated and that the forty-four hour week be retained and more students admitted in preference to lengthening the hours per week with a smaller number of students It has been found in some cases that to admit smaller classes three or four times a year is not as disrupting as to admit one large class Federal grants and existing scholarship funds permit an increase in the number of tuition scholarships

Expansion of auxiliary nurses' services also offers a method of increasing the effectiveness of full trained nurses

The present situation is summed up as follows:

"It seems to me that a survey of the situation confronting us leads to a few simple but ineluctable conclusions

"1 Subsidiary workers on different levels and volunteers may help in great measure to give nursing service, but there is no substitute for the well trained nurse in the administration of nursing care

"2 The maintenance of nursing care may be achieved by

"(a) Using for nursing care many of the hours now spent in activities classed as nursing service

"(b) Eliminating the physical and the administrative factors which waste nurses' time and energy

"(c) Fixing living conditions and salaries for nurses on a level which will keep nurses in the hospitals"

This item is based on material contained in the American Journal of Nursing July 1942 and especially on the work of the biennial session of the American Nursing Association which opened in Chicago in May 1942

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Personal—Dr Aaron J Rosanoff, Sacramento, resigned as director of state institutions effective July 1. Dr Rosanoff has held the position since 1939.—Dr William B Wallace, Rochester, Minn., has been appointed clinical instructor in surgery at the Stanford University School of Medicine, San Francisco.

New School of Humanities at Stanford—The establishment of a School of Humanities at Stanford University has been made possible in part by a grant of \$47,500 from the Rockefeller Foundation. The new school will begin operation in September. Mr Lewis Mumford, New York, author, will be the professor of humanities, the assistant professors will be Arthur E Bestor and Jeffery Smith of Columbia University and Desmond E Powell of the University of Arizona. According to an announcement from the school, in these times it is significant that Stanford University should be emphasizing not only the war effort but also the necessity of facing constructively the whole business of American culture and the necessity for maintaining unshaken that which we are in the very process of defending. John W Dodds, Ph.D., professor of English at Stanford, has been named dean of the new school.

DISTRICT OF COLUMBIA

Luncheon Meetings Proposed—The Medical Society of the District of Columbia has under consideration a plan to replace some of the regular evening meetings during the year with luncheon sessions. It is believed that practitioners are too tired carrying on their practices as well as the many activities the present emergency demands of them to enjoy evening meetings.

Dr Armstrong Returns to Washington—Dr Charles Armstrong, director of the Division of Infectious Diseases, National Institute of Health, Bethesda, Md., has arrived in Washington to be a patient at the United States Naval Hospital, newspapers reported. Dr Armstrong is recovering from a severe attack of tularemia. He was reported ill with the disease shortly after arriving at the Rocky Mountain Spotted Fever Laboratory of the U. S. Public Health Service at Hamilton, Mont.

IDAHO

State Medical Meeting at Sun Valley—The Idaho State Medical Association will hold its annual session in Sun Valley, September 17-19, under the presidency of Dr Paul M Ellis Wallace. The following members of the faculty of the University of Oregon Medical School, Portland will participate:

- Dr Frank R Menne Pathology of Lymph Nodes Pathology of the Prostate Gland and Pathology of Cancer of the Stomach
- Dr Raymond E Watkins Management of Hemorrhage in the Later Half of Pregnancy, Cancer of the Uterus and Treatment of Prolapse of the Uterus
- Dr Lyle B Kingery Present Status of Superficial Fungous Infections of the Skin, Five Day Treatment of Syphilis and Dermatological Problems of the General Practitioner
- Dr Joseph B Bilderback Surgical Conditions of the Abdomen in Infants and Children (with Dr Gius) March of Pediatrics and Vomiting in Infancy
- Dr Edwin E Osgood Principles of Chemotherapy Differential Diagnosis of Coma and Therapeutic Thinking
- Dr John A Gius Surgical Conditions of the Abdomen in Infants and Children (with Dr Bilderback) Cancer of the Colon and Considerations in Treatment of War Wounds

ILLINOIS

Dr Boyd Named Acting Director—Dr Richard F Boyd, assistant to the chief of the division of local health administration, state department of health, was appointed acting chief of the division, effective July 1. He fills the vacancy that occurred when Dr Hugo V Hullerman resigned as chief to become deputy commissioner of health and director of maternal and child health of the Peoria Department of Health. Dr Boyd has been associated with the Municipal Contagious Disease Hospital in Chicago, the Kansas State Board of Health and more recently with the Farm Security Administration as regional medical officer in Michigan, Wisconsin and Minnesota.

CHICAGO

Dr McGuigan Retires—Dr Hugh A McGuigan has retired as professor of pharmacology and therapeutics at the University of Illinois College of Medicine, effective September 1. Dr McGuigan was born in Ireland in 1874. He received his degree of doctor of philosophy at the University of Chicago in 1905, graduating at Rush Medical College three years later. He has served on the staffs of the North Dakota Agricultural College, Fargo, University of Chicago and Northwestern University Medical School and since 1917 has held a professorship at Illinois.

MAINE

Home Study Courses—The Maine Medical Association, at its annual meeting in June, approved a program of home study courses in the specialties, to be available to members on application to Dr Frederick R Carter, 142 High Street, Portland. Committees of recognized specialists will have charge of the courses. Physicians may apply for one or more of the courses, and material will be sent out periodically to each applicant. The program aims to assist in organized reading, suggest pertinent up to date subjects with which the physician should be conversant and provide ready references in the literature.

MICHIGAN

Blood Plasma Banks—Plans are under way to establish blood banks at centers throughout the state for the collection of blood for processing at the state department of health laboratories in Lansing. When a supply has been built up blood plasma will be made available without cost wherever needed. It is hoped to have the general program in operation by Thanksgiving.

Five Deaths in Diarrhea Epidemic—Five patients in the indigent unit in the Eloise Hospital, Detroit, were reported dead and 28 others seriously ill in an outbreak of infectious diarrhea, newspapers reported on August 17. All the patients in the indigent ward were isolated as efforts were made to locate a carrier who was believed to have been responsible for the epidemic.

Memorial Hospital Remodeled—The James W Sheldon Memorial Hospital has been remodeled and refurnished with funds supplied by the city of Albion and the W. K. Kellogg Foundation. An official opening took place on August 9. The hospital, which is owned and operated by the city of Albion, was established in 1924. Its origin, however, began with the establishment of the Wade Hospital in a private home in 1907.

Poliomyelitis Consultation Service—The Michigan Crippled Children Commission will again this year establish poliomyelitis consultation service for physicians desiring it for cases or suspected cases of poliomyelitis in children from birth to 20 years of age inclusive, when the family is financially unable to provide this service and when consultation is not furnished locally. The service will be available until December 1. Dr Carleton Dean, Lansing, is director of the service.

New Regulations of State Health Council—Regulations approved by the state council of health at a recent meeting, prohibit the fitting of shoes to stockungless feet and of foundation garments to women who do not wear underslips, the importation of parrots, parakeets and love birds, and the reuse of metal bottle caps having porous linings. According to *Michigan Public Health* the increase in imports of psittacine birds which may transmit so called parrot fever prompted the readoption of a regulation first having effect in February 1939.

MINNESOTA

Hospital for Kenny Treatment of Infantile Paralysis—St Barnabas Hospital announces the opening of the Sheltering Arms Hospital Minneapolis for the exclusive care of patients with infantile paralysis under the Sister Kenny treatment. The Sheltering Arms Hospital was established in 1882 as a home for orphaned and dependent children. The present accepted theory of placing orphaned children with families rather than in institutions has lessened the social usefulness of this institution, and a decision to devote it to the Sister Kenny treatment ends a series of negotiations involving the trustees of the Sheltering Arms Hospital, the board of directors of the St Barnabas Hospital and the War Production Board. The hospital is located on a 29 acre tract and construction on the remodeling of the building will start immediately. Privately interested persons have already given the \$30,000 which is needed at present to finance the project. It is expected that the hospital will be in operation some time in September. A special wing will be devoted to patients in the initial and contagious stages of the disease. St Barnabas

will operate Sheltering Arms and Dr Wallace H Cole professor and director of the department of orthopedic surgery and Dr Miland E Knapp, head of the department of physical therapy, University of Minnesota Medical School, Minneapolis, will be in charge of the staff

MONTANA

State Medical Election—Dr John P Ritchey Missoula, was named president-elect of the Medical Association of Montana at its annual meeting in July. Drs Ernest D Hitchcock Great Falls, was installed as president and Arthur C Knight Philipsburg, vice president. Dr Thomas F Walker Great Falls, is the secretary. The 1943 session will be held at Billings.

NEBRASKA

Tenth Annual Clinical Assembly—The Omaha Mid West Clinical Society will conduct its tenth annual clinical assembly at the Hotel Paxton, Omaha, October 26-30. One session will be devoted to a consideration of "Newer Concepts Regarding Hypertension and Its Treatment." The preliminary program lists the following physicians as speakers:

Frederic W Bancroft New York	Herman H Riecker Ann Arbor
Samuel Iglauer Cincinnati	Mich
William J Dieckmann Chicago	Philip D Wilson New York
Irvine H Page Indianapolis	Arvid F Hansen Minneapolis
Elmer L Sevringhaus Madison	Francis E Sencar Chicago
Russell L Haden Cleveland	Temple S Fry Philadelphia
Frank H Lacey Boston	Harry M Weber Rochester Minn

NEW JERSEY

Housing Project Quarantined for Infantile Paralysis—Seth Boyden Court Newark's second largest housing project with 530 families with about 1000 children was placed under quarantine on August 15 after 3 children of residents there were stricken with infantile paralysis. According to the New York Times the order permitted adult workers and shoppers to enter and leave their homes but children were to be confined within limits of the project for twenty-one days. No family will be permitted to have visitors. The quarantine was ordered by Dr Charles V Craster health officer of Newark. Notices were posted at 8 o'clock in the morning and nurses and physicians began an immediate check on children in the buildings. Two of the cases were reported early the previous week and the third was confirmed on Friday August 14. The stricken children, 4, 5 and 7 years of age were taken to Essex County Hospital for Contagious Diseases, Belleville. Dr Craster said the cases might have resulted from 13 cases of poliomyelitis that caused two deaths in Union County in recent weeks. The New Jersey state health department described the state situation as normal in reporting a total of 35 cases in eight counties, most of them in Union County, since July 1 and a total of 44 since January 1.

NEW YORK

Research Program in Cancer—The establishment of a research project is now being contemplated by the Westchester Cancer Committee according to the *Westchester Medical Bulletin*. It is hoped to obtain a starting fund of \$5000 to begin the work early this fall. Dr Gilbert Daildorf, Valhalla, chief pathologist at Grasslands Hospital has been appointed chairman of a newly appointed committee on research to carry out the project.

Course in Tuberculosis—The Trudeau School of Tuberculosis announces its twenty-eighth session, September 14-October 9 at Saranac Lake and a supplementary course October 12-23, at Bellevue Hospital, New York. Students completing the four weeks at Saranac Lake may take the extra study in New York without additional charge. The general plan aims to present the essentials of history etiology epidemiology, pathology, diagnosis prognosis and treatment during the four weeks at Saranac Lake. Emphasis is placed on bedside teaching and the clinical study and treatment of patients combined with x-ray and pathologic conferences. The course at Bellevue is planned to afford a survey of the diseases of the chest as they are encountered in practice. Pathology and pathogenesis will be illustrated with specimens of morbid anatomy and with clinical cases.

New York City

Chinese Science Society—The Science Society of China organized at Cornell University in 1914 and later established in China has formed a New York chapter to promote better understanding and cooperation among Chinese research workers in the United States. Among the chapter officers are John

Y C Watt president, Chek M Soo Hoo, vice president, and Dr Katherine Li, member of the committee.

Dr Wegman Appointed Director of Research—Dr Myron E Wegman assistant professor of child hygiene in the School of Tropical Medicine, San Juan, Puerto Rico, has been appointed director of training and research in the bureau of child hygiene of the city department of health. Dr Wegman filled the vacancy left when Dr Albert S McCown resigned to become medical director of the American Red Cross. Dr Wegman graduated at Yale University School of Medicine, New Haven in 1932 and served for a time as pediatric consultant in the Maryland State Department of Health.

Ledyard Fellowship Available—The Society of the New York Hospital announces the Lewis Cass Ledyard Jr Fellowship which is available to an investigator in the fields of medicine and surgery or in any closely related field. Preference will be given to younger applicants who are graduates of medicine and who have demonstrated fitness to carry on research of high order. The fellowship was established in 1939 in honor of Lewis Cass Ledyard Jr governor of the New York Hospital. The income amounts to approximately \$4000 annually. \$3000 will be used as a stipend and about \$1000 for supplies for research. Applications for the fellowship should be in the hands of the committee by December 15, and it is expected that the award will be made by March 15 and the fellowship itself to be available July 1. Applications should be addressed to the committee of the Lewis Cass Ledyard Jr Fellowship Society of the New York Hospital, 525 East Sixty Eighth Street, New York.

OREGON

Industrial Hygiene Unit—Plans have been under way to establish an industrial hygiene unit in Oregon. According to *Industrial Hygiene* Dr Harold F Castberg formerly acting chief of the Industrial Hygiene Service of California at Berkeley and Mr I F Charnett his associate, are organizing the unit in the state, which thus far has not provided health services for its industrial workers.

Annual Session Limited to Meeting of House of Delegates—The Oregon State Medical Society, in view of the present emergency has decided to limit this year's annual session to meetings of the house of delegates and the general society to transact necessary annual business. The meeting will be held in Portland, September 12-13. The program of papers has been canceled with the exception of those contributed through the courtesy of the Portland Academy of Medicine to be presented by Dr George Fair professor of internal medicine, University of Minnesota Medical School, Minneapolis. The titles of the lectures are "What Is Congestive Heart Failure?" "The Rational Treatment of Congestive Heart Failure" and "The So-Called Irritable Heart of the Soldier."

PENNSYLVANIA

Dr Schneider Wins Scholarship in Tuberculosis—Dr Benjamin Schneider Danville, was recently chosen by the Pennsylvania Tuberculosis Society as the recipient of its annual scholarship at the Trudeau School for Tuberculosis at Saranac Lake New York. The scholarship is always given to a physician in general practice. Dr Schneider who graduated at the University of Pennsylvania School of Medicine Philadelphia in 1933, has engaged in general practice in Danville and surrounding rural territory the past eight years. He was president in 1940 of the Montour County Medical Society. In addition to this scholarship Dr Schneider has been awarded one of the annual scholarships of the Trudeau School in an amount sufficient to cover the tuition fee. The course will open this year on September 14 and as usual will run four weeks at the school with the privilege of two additional weeks at the Bellevue Hospital in New York.

Philadelphia

Personal—Dr William H Schmidt has been appointed associate professor of physical therapy at Jefferson Medical College of Philadelphia.—Dr Alfred N Richards, professor of pharmacology University of Pennsylvania has been elected a foreign member of the Royal Society of London, according to *Science*.

Two Million Dollar Bequest to Cancer Institute—Lankenau Hospital Cancer Research Institute will receive nearly \$2,000,000 from the estate of Mrs Anna C Burr, who died on March 6. The bequest which will be used for the study of cancer will serve as a memorial to Mrs Burr's husband, Edward H Burr, who died in 1922.

Pittsburgh

New Psychiatric Hospital—The state department of welfare announces the opening soon of the Western State Psychiatric Hospital on the campus of the University of Pittsburgh. The purposes of the hospital will be the treatment of patients, research in neurology and psychiatry training of medical students, physicians and workers in allied fields. The hospital will accommodate 250 beds. Eight floors have been set aside for the care of psychotic adults and children.

TEXAS

Radiologist Honored—A bronze plaque was presented to Dr. James M. Martin, Dallas, on June 5 by Major Glenn D. Carlson, M. C., U. S. Army, Fort Sam Houston, on behalf of the Texas Radiological Society in appreciation of his fifty years' service in the practice of medicine and particularly to mark his activities in the field of radiology. The presentation was made in Dr. Martin's room in Baylor University Hospital, where he had been a patient for several weeks, according to the state medical journal. Earlier in the year the society had adopted a resolution paying tribute to Dr. Martin.

Portraits Presented to Medical School—Portraits of Drs. William S. Carter and the late Harry O. Knight, purchased by the University of Texas Medical Alumni Association, were recently presented to the University of Texas Medical Branch, Galveston. Dr. Carter was appointed to the school in 1897 as professor of physiology; he served as dean from 1903 to 1922 and again from 1935 to 1938. Dr. Knight graduated at the school in 1907 and joined the faculty in 1909 as demonstrator of pathology, bacteriology and anatomy. He was adjunct professor of anatomy from 1914 to 1923, when he became professor of anatomy, a position he held at the time of his death in 1939.

VIRGINIA

Physician President of Chamber of Commerce—Dr. Huston St. Clair, Tazewell, was recently chosen president of the Virginia State Chamber of Commerce. Dr. St. Clair graduated at the University of Pennsylvania School of Medicine, Philadelphia, in 1926. One of his first projects will be to name a committee to carry out the long time study of the state educational system in relation to the needs and to the progress of education in other states, newspapers report.

Legislative Committee Appointed to Study Medical Licensure—On March 9 Governor Darden approved a joint resolution passed by the general assembly creating a commission to develop a comprehensive plan for examining and licensing persons seeking to practice any branch of the healing art in Virginia and for preventing unqualified persons from so practicing. This commission is to report its findings and recommendations to the general assembly at least sixty days before the convening of the next regular session. The joint resolution provides that this commission shall be composed of seven members, two to be appointed by the president of the senate from the members of the senate, three by the speaker of the house of delegates from the members of the house and two by the governor. All appointments have now been made. Governor Darden appointed Dr. Edgar Gammon, president of Hampden-Sydney College, and Lawrence Peyton of Staunton as two members. The president of the senate appointed Senator James D. Hagood of Colver and Senator Garland Gray of Waverly. The speaker of the house of delegates appointed the following members of the house to serve on the committee: Stuart B. Campbell of Wytheville, John B. Boatwright of Buckingham and Walter H. Scott of Roanoke.

WEST VIRGINIA

Society News—Dr. Andrew E. Amick, Charleston, discussed Infantile Diarrhea with Special Consideration as to Differential Diagnosis and Treatment, before the Fayette County Medical Society in Montgomery, June 16. The Cabell County Medical Society was addressed in Huntington on June 11 by Dr. Ralph F. Bowers, New York, on 'Operative Treatment of Carcinoma of the Sigmoid Involving the Urinary Bladder'.

State Medical Election—Dr. Robert J. Wilkinson, Huntington, was chosen president-elect of the West Virginia State Medical Association at its annual meeting in Huntington in July and Dr. Richard O. Rogers, Bluefield, was installed as president. Vice presidents are Drs. William T. Goeke, Clarksburg, and John C. Lawson, Williamson. Mr. Charles Lively, Charleston, is the executive secretary. The 1943 session will be held at White Sulphur Springs.

GENERAL

Meeting Canceled—The American Psychological Association canceled its fiftieth anniversary meeting, which was scheduled to be held in Boston and Cambridge the first week in September. A business meeting was to be held in New York City on September 3.

Obstetricians Suspend Meeting—The Central Association of Obstetricians and Gynecologists voted to suspend its meetings for the duration of the war and has canceled its meeting scheduled for Des Moines, Iowa, October 22-24. The officers of the association will remain as at present until the next meeting. On resumption of meetings the first one will be scheduled for Des Moines and the next one for Louisville, Ky. Drs. John H. Moore, Grand Forks, N. D., is president, Earl C. Sage, Omaha, president-elect, and William F. Mengert, Iowa City, secretary-treasurer.

Biological Photographic Association—The twelfth annual meeting of the Biological Photographic Association, Inc., will be held at the Park Central Hotel, New York, September 10-12. The program will include a discussion of trivision color photography, latent image stability, photography of small objects, SM flash lamp in clinical photography, botanic and zoologic photography, and photographic equipment in the army and navy. Lieut. Ralph Creer, in charge of the medical illustration section of the army medical corps, will discuss the use of medical illustration in wartime and Ensign Warren Sturgis, naval medical films.

Roentgen Ray Society Meeting—The American Roentgen Ray Society will hold its annual meeting at the Palmer House in Chicago, September 15-18, under the presidency of Dr. William M. Doughty, Cincinnati. Included among those who will participate are:

- Dr. Paul C. Swenson, New York: Roentgen Diagnosis and Therapy of Ewing's Tumors.
- Dr. Charles A. Behney, Philadelphia: Further Evaluation of 200 Kilo volt Roentgen Rays in the Therapy of Carcinoma of the Cervix Uteri.
- Dr. Laurence L. Robbins, Boston: Spray Irradiation of Polyesthermia Vera.
- Dr. W. Walter Wasson, Denver: Intrapulmonary Air Pressure and Its Relation to Pulmonary Capillary Flow.
- Dr. Lewis Gregory Cole, New York: Pneumonoultramicroscopic Silicovulcanosis: Highlights and Lowlights in the Story of Dusty Lungs.
- Dr. Elmer J. Bertin, Philadelphia: Metastasis to Bone as the First Symptom of Gastrointestinal Carcinoma—Report of Three Cases.
- Dr. Robert B. Taft, Charleston, S. C.: Ionization Oculogram.
- Dr. Eugene P. Pendergrass, Philadelphia: Some Considerations Concerning the Reports of Deaths and Shocks After the Intravenous Use of Dye in Urography.
- Dr. Arthur U. Desjardins, Rochester, Minn.: A Group of Persons Whose Skin and Subcutaneous Tissues Are Usually Sensitive to Roentgen Rays.

Obstetricians, Gynecologists and Abdominal Surgeons—The fifty-fifth annual meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons will be held at the Homestead, Hot Springs, Va., September 10-12, under the presidency of Dr. Grandison D. Royston, St. Louis. Among the speakers will be:

- Dr. Carl H. Davis, Wilmington, Del.: Hypothyroidism as a Problem in Women—Second Report.
- Dr. Louis H. Douglass, Baltimore: Medical Complications of Pregnancy and Labor.
- Dr. Edward A. Schumann, Philadelphia: Comments on Certain Phases of Surgical Technique.
- Dr. Tiffany J. Williams, Charlottesville, Va.: Hydatidiform Mole and Associated Tumors of the Chorion.
- Dr. Harold I. Cuneo, Kansas City, Mo.: Postpartum Observation of Pelvic Tissue Damage.
- Dr. Clyde L. Randall, Buffalo: Sarcoma of the Uterus.

The Foundation Prize Thesis will be given Thursday evening by Dr. Harold C. Mack, Detroit, on 'The Glycogen Index in the Menopause: A Study of Certain Estrogen Functions Based on a New Method of Staining Vaginal Smears'.

President's Birthday Fund for Infantile Paralysis—A total of \$3,508,310 was collected during the national celebration of the President's birthday last January. The expenses of the committee were \$207,889.71 or 5 per cent of the total net amount raised. New York led the states with contributions of \$663,646.19. California was second with \$337,318.79 and Pennsylvania third with \$296,843.99. Illinois was fourth with a total of \$202,352.04 and Ohio fifth with a total of \$202,236.65. Theaters raised a total of \$1,338,059.59. One half of the proceeds collected in the annual President's birthday celebration goes to the National Foundation for Infantile Paralysis, whose share is used to sponsor clinical and laboratory research on the disease, provide epidemic and conduct an educational program for both the general public and the medical profession. The other 50 per cent of the funds remains with the state and county chapters of the foundation where it

is used to provide direct medical assistance to infantile paralysis patients regardless of age. In the four years since the establishment of the chapter plan a total of \$4,750,924.35 has been left in the localities throughout the United States and its possessions.

Conference on Tuberculosis—The Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Trudeau Society will hold their annual sessions at the Edgewater Beach Hotel Chicago September 16-18. On Wednesday afternoon a special session will be devoted to exploring channels for tuberculosis education that contribute to child health, at which a group of experts will answer questions. A joint session with the Trudeau Society on Thursday will be addressed by

Dr. Julius B. Novak, Chicago, Tuberculosis Case Finding in Industry by a Tuberculosis Association
Dr. Oscar A. Sander, Milwaukee, Surveying Industrial Personnel
William A. Doppler, Ph.D., New York, Problems Encountered in Organizing Case Finding in Industry and Some Possible Solutions
Drs. Oscar Lotz, Milwaukee, and Loren I. Collins, Ottawa, Ill., The Tuberculin Test and Tuberculosis Control
Dr. J. Arthur Myers, Minneapolis, County Accreditation for Tuberculosis Control
Dr. Herman E. Hilleboe, Washington, D.C., Tuberculosis Control and National Defense
Dr. Herbert L. Muntz, Kansas City, Mo., Incidence of Tuberculosis Among Civil Defense Personnel
Dr. James H. Stigall, Indianapolis, Reinfection Tuberculosis in Younger Children

One feature of a joint session will be a discussion of the 'Results of an Adequate Follow-Up of Selective Service Rejectees.' At the Trudeau Society meeting on Friday the speakers will include Drs. Morris C. Thomas, major, U.S. Army, Fort Knox, Ky., on 'Types of Lung Pathology Encountered in an Army Camp,' Paul D. Grimm, Evansville, Ind., 'Results of Pepton-Agar Feeding in Gastrointestinal Tuberculosis,' John D. Steele, Jr., Milwaukee, 'Bronchospirrometry,' and William R. Lovelace, II, and Horton C. Hinshaw, Rochester, Minn., 'Effect of Reduced Barometric Pressure on Pneumothorax.'

Extension of Latin American Health Program—The assignment of three physicians to Latin America is another step in the health program recommended at the conference of American foreign ministers held early this year in Rio de Janeiro. Dr. Leonard S. Rosenfeld, New York, was assigned to Nicaragua. Dr. Eugene P. Campbell, whose headquarters will be at San Jose but who will carry on a roving assignment throughout Central America, and Dr. Albert R. Dreisbach, lieutenant colonel, U.S. Army, Washington, D.C., who has been assigned as assistant to Dr. George C. Dunham, lieutenant colonel, U.S. Army, director of the entire health and sanitation program now being carried out in Latin America. The project originated from a recommendation made at the inter-American conference and is designed to support American hemisphere economic mobilization and become the foundation for long range health and sanitation improvements in the cooperating countries. The first step was the appointment of Dr. Dunham early in the spring of this year, and one of his first activities was the institution of a program for malaria control in Ecuador. Dr. Walter C. Earle is in charge of this project. Recently Dr. Dunham conferred with Brazilian authorities to work out some health plan incident to the problems of gathering wild rubber on stretches of the Amazon River and its tributaries beyond reach of ordinary health facilities. The most recent step in the project announced July 28 was the assignment of a health and sanitation mission to Bolivia under the direction of Dr. Eugene H. Payne, accompanied by Dr. Wendell S. Dove, acting director of the health and sanitation division of the Office of Inter-American Affairs. The Bolivia mission is the eleventh health and sanitation party organized to collaborate with the other Americans under the original program.

Report on Accidents—According to the annual yearbook of the National Safety Council entitled 'Accident Facts,' 102,500 persons were killed in accidents in 1941. Motor vehicles accounted for 40,000 deaths and accidents in the home for 31,500. Motor accidents were responsible for injuring 1,450,000 persons and accidents in the home for 4,650,000. Other public accidents of all kinds were responsible for the deaths of an additional 15,000 persons and the injuries of 1,800,000. The National Safety Council points out that 97 per cent of the total accidents were preventable and cost the nation \$4,000,000,000. On the job accidents killed 18,000 workers, injured 1,600,000, cost \$850,000,000 and resulted in the loss of 460,000,000 man-days of work during 1941. Every type of motor vehicle accident except collisions with street cars showed a higher fatality total in 1941 than 1940. The bulk of the total increase came in collisions between motor vehicles, which were up 24 per cent, collisions with bicycles, up 20 per cent, collisions with

fixed objects, up 23 per cent, and non collision accidents up 21 per cent. Deaths from motor vehicle train collisions at grade crossings numbered 1,834 in 1941. This was even fewer than occurred in 1923 when motor vehicle travel was only a fraction of its present volume and when far fewer trains were operating than in the preparation for defense period of 1941. The release pointed out that of thirty-one industries studied the aeronautics industry was among the top five for 1941 in terms of both accident frequency and severity. Workers in the aeronautics industry suffered only 740 disabling injuries per million man hours as compared with an average of 15.39 for all thirty-one industries. Of the 40,000 persons who were killed in automobile accidents 8,000 or one in five had been drinking. State summaries for 1941 showed that 11 per cent of the drivers involved in fatal accidents had been drinking and that 14 per cent of the pedestrians killed had been drinking. 1,900 of the 13,600 pedestrian deaths. Summaries for the twenty-two states showed 27 per cent more drinking drivers than were involved in fatal accidents for 1940.

LATIN AMERICA

Defense Health Conference—The eleventh Pan American Sanitary Conference will be held in Rio de Janeiro, September 7-18. The subjects to be discussed at this conference will be continental defense and public health, tuberculosis and pneumoconiosis, influenza, brucellosis (undulant fever), typhus fever, American parasitoses (especially Chagas disease and pinto), diarrheas (including Salmonella infections) and degenerative diseases (especially cardiovascular diseases and cancer). Reports will also be presented by the Pan American committees on nutrition, malaria and model sanitary code.

CORRECTIONS

Misplaced Headings in Educational Number—In THE JOURNAL August 15 the Educational Number, on page 1333 the column headings under 'Orthopedic Surgery—(Continued)' should have been under 'Pathology' instead.

On page 1335 the column headings under 'Pathology—(Continued)' should have appeared under 'Pediatrics' instead.

Memorial Fund to Dr. Martha Tracy—The American Medical Women's Association writes that erroneous information appeared in the news item in THE JOURNAL August 22, page 1436 concerning the memorial fund to Dr. Martha Tracy. According to Dr. Helen T. Ratterman, president of the association voted at its meeting in Atlantic City to pay tribute to the memory of Martha Tracy by establishing a fund to be used at the Woman's Medical College of Pennsylvania, Philadelphia. Dr. Lucille Snow, Evanston, Ill., is chairman of a committee in charge of the fund. *Women in Medicine* is the official journal of the American Medical Women's Association and not the *Medical Woman's Journal* as reported in THE JOURNAL news item.

Government Services

Dr. Hauser Named Assistant of Census Bureau

Philip M. Hauser, Ph.D., Washington, D.C., formerly assistant chief statistician for population, has been appointed assistant director of the Census Bureau and will have under his supervision the divisions of vital statistics, population and housing, agriculture and state and local government.

CCC Camps to Become Hospitals for Girls with Venereal Disease

More than twenty-five camps formerly used by the Civilian Conservation Corps, which has been abolished by Congress, will be used as detention centers and quarantine hospitals to cure and rehabilitate girls infected with venereal diseases, it was announced August 27. The CCC hospitals will be operated by health departments of the various states under standards of medical care recommended by the U.S. Public Health Service. Camps have already been made available in Alabama, Florida, Georgia, Louisiana, Mississippi, New Mexico, Oklahoma, South Carolina, Tennessee, Texas and Virginia. Each hospital is expected to provide medical treatment for 100 to 300 infected girls, who will be kept under care until they are rendered non-infectious and completely cured. Federal assistance will be given to place these girls in legitimate industry when they leave the hospitals.

Sluicing of Streams as an Emergency Antimalarial Measure

Sir Malcolm Watson, director of the Ross Institute of Tropical Medicine, has described in a booklet, issued by the institute, some antimalarial measures in use in Malaya. The loss of the Dutch oil fields to the Japanese has interrupted the supply of oil which killed larvae in running water and saved thousands of lives. The construction of the Panama Canal and the extension of the rubber industry in Malaya depended on the use of oil. Attention has now to be turned to the alternative of sluicing for the destruction of larvae. If this should prove effective for only a few months in the malarial season it would help in winning the war. The use of sluicing dates back to the work of Prof K B Wilkinson in 1930-1932 at Cameron Highlands, Malaya, in destroying *Anopheles maculatus* under difficult conditions. He showed that simple forms of tipplers and sluices destroyed larvae in all the local streams and drains and that after a time the adult *Anopheles* disappeared. In 1937 Sir Malcolm Watson visited Penang and found that nearly two hundred streams were being flushed along 15 miles of the hill which rises out of the center of the island. Some of the sluices were automatic, others hand operated. Formerly so malarial as to be only sparsely inhabited, this area had been practically freed from malaria and land values had gone up. From Penang flushing spread through the Malay Peninsula not only in mountain streams but in almost flat land drains. The method has also been adopted in India. Mr J S De Villiers, chief sanitary inspector of Penang, has devised the simplest form of automatic siphon for antimalarial sluicing. It consists of a disused oil drum which stands inverted on three concrete blocks above the dam, a main siphon which runs under the dam and a secondary siphon made of $\frac{3}{4}$ inch galvanized iron pipes. When the water rises behind the dam it rises also in the drum, because air passes out through the secondary siphon. Also water flows through the secondary siphon and sucks more air out of the drum. When the water in the drum rises high enough it splashes over the main siphon, which in less than a minute discharges a torrent that flushes the stream.

Rehabilitation After Injuries of the Central Nervous System

Rehabilitation after injuries of the central nervous system has received insufficient attention. Cases are seldom seen by a neurologist until many months have elapsed when a neurosis may have been established. The great number of war injuries has increased the importance of the subject. In an address to the Neurological Section of the Royal Society of Medicine on rehabilitation after injuries to the central nervous system Prof Geoffrey Jefferson referred to our increasing knowledge of the mechanism of headache and abandonment of belief in the relation between pressure and headache as against local distortions of dural septums and traction on, or pulsation of, vessels. After head injuries rehabilitation should begin in the convalescent stage of treatment in the hospital and be planned to give not only physical but mental employment day by day. It gives the patient the opportunity to discover that his wage earning capacity is not lost and allow him to turn to another occupation more fitted for his powers. Hitherto rehabilitation had been applied only sporadically and not systematically. It should begin a graded way as soon as the patient's condition

allows. The methods included (1) diversional and constructive occupations of sufficient variety for those still confined to bed as well as for those who are ambulant, (2) hospital maintenance work in the ward and outside, (3) physical therapy remedial exercises, massage and physical training and (4) intellectual and recreational pursuits.

Rehabilitation may be divided into two stages. The first covers the period in the hospital the patient being confined to bed or ambulatory. Rehabilitation in a diversional form should be instituted early while the patient is confined to bed. It takes the form of reading or being read to, *scrabble*, crossword and other puzzles, drawing or coloring, needlework, string bead and basket making, sewing, knitting and rug making. In most cases of dysphasia the retraining of speech by a speech therapist should be started when convalescence is well established, about the third or fourth week. Physical therapy (massage, electricity and gymnastics) will be required but should not dominate the rehabilitation scheme. Mental occupation and encouragement to do things are more important. This stage will last about six weeks. The second stage is a period of hardening, once symptoms have abated. Military cases should be taken over by the respective services, since this means canalization toward special work. For civilian cases the treatment consists in gymnastics and physical training, continuation of some of the occupations mentioned, work in the garden, or carpenter's or engineer's shop, organized games, visits to the town, shops and the cinema. But no patient with a head injury should go on a bus or train journey until he has proved his ability to do this.

Brazilian Typhus Fever Virus

Prof Octavio Magalhaes and Dr Adir Rocha from the University of Belo Horizonte, state of Minas Gerais, have published a paper describing a careful analysis of 228 samples of Brazilian typhus fever virus. They reached the conclusion that there are at least three main strains of typhus virus into which it is possible to classify all the different samples up to now isolated from man or animals as patients, with severe or light disease or as simple carriers of the virus. They have called these strains VB, VA₁ and VA. The strain VB is the virus of the typical Brazilian typhus showing very constant characters. The other two are attenuated strains. The classification has been done by taking into consideration twelve classes of research: (1) incubation time in the experimental disease, (2) duration of the experimental disease, (3) reactions of the susceptible animals (thermic testicular vulvar, splenomegaly, peritoneal and ganglionic), (4) percentage of death in the experimental disease, (5) susceptible animal (guinea pig, rabbit and rhesus monkey), (6) cross immunization, (7) precipitation tests, (8) resistance to freezing and to glycerin, (9) Weil Felix reactions in the natural and the experimental disease, (10) pathologic findings (microscopic and macroscopic), (11) presence of Rickettsiae and (12) pathogenicity to man.

Myxomatosis Transmitted by Mosquitoes

Dr Henrique Aragao of the Oswaldo Cruz Institute read before the Brazilian Society of Biology a note on the transmission of the virus of myxomatosis (*Chlamydozoon myxomicum*) by mosquitoes of the species *Aedes aegypti* and *Aedes scutellaris*. The Brazilian wild rabbit (*Silvillagus municeps*) is susceptible to the virus of myxomatosis but in this animal the disease takes a milder character, lasts a long time and in general does not kill the rabbit. As a rule the tumors are smaller and less numerous than those of the domestic rabbit but large and

flat lesions have been noted. A few of these animals caught in the forests were sick with the disease but many of them were found to be immune. The experimental infection of the wild rabbit may be easily obtained by cutaneous, subcutaneous and conjunctival inoculations and also by placing a healthy wild rabbit in the same cage with a sick domestic animal. It is also possible to obtain the infection of the wild and domestic rabbits by the bite of infected blood sucking insects as fleas and mosquitoes. The infected mosquito can transmit the disease several times in succession up to at least seventeen days after it has fed on a sick rabbit as has been observed by Arago. The transmission is purely mechanical, and only the proboscis of the insect contains the virus, as has been shown by the inoculation of emulsions of the proboscis, the thorax and the abdomen of the mosquito. Though mechanical, this kind of transmission has epidemiologic significance as this means of dissemination easily explains the sudden outbreaks of myxomatosis in animals breeding in places where there have been no rabbits for a long time. It was Arago who at first pointed out the transmission of myxomatosis by fleas (*Stenopsylla*). Some time later Torres, also of the Oswaldo Cruz Institute, showed that the mosquito *Culex quinquefasciatus* is capable of transmitting the disease. Now again Arago has demonstrated that *Aedes aegypti* and *Aedes scapularis* mosquitoes are able to transmit myxomatosis. The virus is seen in smears of material from the tumors of wild rabbits with the same morphology as in material from domestic animals.

Blood Banks in Palestine

Many years before the outbreak of war, this country was faced with the problem of how to supply the necessary quantities of blood required for transfusions. When the disturbances first began in Palestine in 1936, that is, before we had the opportunity to benefit from the experience of the civil war in Spain, we were forced to seek a solution to the question of blood transfusions and to discover a means for conserving and storing blood at a time when these problems were receiving little or no attention in European countries or in the United States. Quite apart from the general difficulties involved in the conservation of blood, we were confronted with specific medical and organizational problems due to the special conditions of this country.

After several preliminary tests, the first store for conserved blood in Palestine, and perhaps in the Middle East, was set up in the Beilinson Hospital (of the Kupat Holim) in 1938. The first source of blood was the blood obtained from the placenta in maternity cases. From this store blood was supplied for all the requirements of the Beilinson Hospital, which at that time were greater than usual owing to the excessive casualties in the vicinity resulting from the disturbances. Soon the conserved blood of adults began to be used, while placenta blood was used for other therapeutic purposes (endocrine treatment for amenorrhea and sterility). At the end of 1939 the use of plasma of the placenta was commenced, and shortly afterward the plasma of other blood with entirely satisfactory results. Up to the present six hundred transfusions of conserved blood and four hundred plasma transfusions have been administered without a single unfavorable reaction such as hemoglobinuria or anuria. The percentage of reactions, including chills was, generally speaking, about 8 per cent for blood transfusions and much less for plasma transfusions.

The problem of malaria is acute. While there is great variation in the incidence of this disease as between one district and another and particularly as between rural and urban districts, the total number of malaria cases, in the past and in the present,

is high. Before the use of conserved blood for transfusions was begun much difficulty was often experienced in obtaining supplies of blood from persons who had never had malaria, especially in such malarial districts as Emek Jezreel and Galilee. With the introduction of conserved blood for transfusions, this problem has been solved. It seems probable that the maintenance of the conserved blood at a low temperature destroys all the malarial plasmodia, and there is no longer any hesitation in accepting blood from donors who had suffered from malaria in the past. No adverse effects from the use of such blood have so far resulted.

Today nearly all public hospitals in the country have their own blood banks, the blood being taken in most cases from the members of the families of the patients. In addition supplies are available from organizations of volunteer blood donors from whom large quantities of blood may be taken if the banks should become exhausted.

Rothschild-Hadassah-University Hospital, Jerusalem

Following the outbreak of the war and the deterioration of the economic situation in Palestine, the activities of the Rothschild-Hadassah-University Hospital were greatly extended. The number of beds in the hospital was increased from 215 in May 1939 to 325 in May 1942 and, in addition, 200 reserve beds are kept in readiness for emergency cases.

A neurosurgical department was opened in the Rothschild-Hadassah-University Hospital at the beginning of 1942. This department is headed by Dr. Henry Wigderon, a neurosurgeon from the United States who worked previously as assistant to Dr. Sachs of St. Louis and later as neurosurgeon in several New York hospitals. The need for a neurosurgical department in the Near East was acutely felt after the outbreak of the war. Before the war, neurosurgical cases had usually been directed to European capitals. The opening of this department in the Medical Center is another step toward the extension of its scientific work and the complementing of therapeutic facilities in the surgical field in the Near East. Since the department was opened it has treated a considerable number of patients, both local and from neighboring countries.

In 1940 occupational therapy was introduced in the Rothschild-Hadassah-University Hospital, which is the only general hospital in Palestine engaged in this activity. Occupational therapy is given especially in skin and radium cases as well as in the pediatric and other departments.

In connection with the war situation research work on the treatment of complicated wounds has been undertaken by the surgical divisions in conjunction with the department of pathologic anatomy of the Hebrew University.

An underground air raid shelter has been constructed in the hospital grounds which can accommodate a large number of patients and personnel. Fortunately there has been no need to make use of it so far, except for alarm practice.

Congress of Nerve Specialists in Tel Aviv

After an interval of several years during which scores of physicians from various European countries have found their way to Palestine and begun to practice in this country, the second Congress of Nerve Specialists took place in Tel Aviv on April 17. About seventy-five nerve specialists from Jerusalem, Haifa, Tel Aviv and other parts of Palestine as well as many other physicians, took part. A number of British and Australian physicians now serving with the forces were also present as guests. One of the principal subjects discussed was "Methods of Psychiatric Treatment Through Shock of Cases of Schizophrenia." The second subject was the "Present Situation in Surgery of the Brain," on which Dr. Vigdorson delivered a comprehensive address. Other subjects of discussion included various neurologic and psychiatric problems.

Deaths

Hugo Ehrenfest * St Louis, Medizinische Fakultät der Universität Wien, Austria, 1894, assistant professor and professor of gynecology and obstetrics at St Louis University School of Medicine from 1904 to 1920 associate professor of obstetrics at the Washington University School of Medicine from 1922 to 1926 professor of clinical obstetrics and gynecology from 1926 to 1936 and since then professor emeritus specialist certified by the American Board of Obstetrics and Gynecology, Inc member of the American Gynecological Society and the Central Association of Obstetricians and Gynecologists, fellow of the American College of Surgeons, gynecologist to the Jewish Hospital associate obstetrician to St Louis Maternity Hospital, editor, *American Journal of Obstetrics and Gynecology*, aged 72, died, July 24, of coronary thrombosis

Clinton G Hickey, Denver, Albany (N Y) Medical College, 1884, member of the Colorado State Medical Society member of the faculty of the University of Colorado School of Medicine during 1896-1897 and later instructor of physical diagnosis at the Denver and Gross Medical College, from 1915 to 1921 member of the Colorado State Board of Health, and its president, 1919-1920, past president of the Denver Clinical and Pathological Society treasurer from 1921 to 1923 of the Medical Society of the City and County of Denver and president in 1925, aged 83, died, May 20, in St Luke's Hospital of arteriosclerosis

Nelson Shelly Weinberger * Sayre, Pa, Medical-Chirurgical College of Philadelphia, 1905 member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology, Inc, member and formerly vice president of the American Laryngological Rhinological and Otolological Society, fellow of the American College of Surgeons, specialist certified by the American Board of Otolaryngology, ophthalmologist and otologist to the Robert Packer Hospital, aged 60, died, June 28, of glioma

Augustus Joseph Hambrook * Troy, N Y, Albany Medical College, 1907, past president and secretary of the Medical Society of the County of Rensselaer served as a captain in the medical corps of the U S Army during World War I in 1937 was appointed a member of the state advisory council on health and physical education in public schools, medical consultant in the city department of public welfare on the staff of the Troy Hospital, aged 59 died, July 13, in the Homer Folks Tuberculosis Hospital, Oneonta

Thomas Albert Bryan * Mattoon, Ill, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1903, fellow of the American College of Surgeons, medical examiner for the local draft board, served as a captain in the medical corps of the U S Army during World War I, on the staffs of the Methodist Memorial Hospital and the Independent Order of Odd Fellows Old Folks Home Hospital, aged 63, died, June 16, of coronary occlusion

Aaron Locke Higgins * Rockville Centre N Y, Tufts College Medical School, Boston, 1907 past president of the Nassau County Medical Society, fellow of the American College of Surgeons for many years chief surgeon and president of the board of the Mercy Hospital, on the staff of the South Nassau Communities Hospital, consulting obstetrician to the Meadowbrook Hospital, Hempstead, attending obstetrician to the Nassau Hospital, Mineola, aged 58, died, July 17

Ernest Leonard Schroeder * Shawano, Wis, Northwestern University Medical School Chicago, 1914, president of the Shawano County Medical Society formerly mayor of Shawano, served as a major in the medical corps of the U S Army during World War I, on the staff of the Municipal Hospital, formerly member of the board of visitors of the University of Wisconsin, Madison, chairman of the Shawano County Council of Defense, aged 56, died, July 7

Thomas Chalmers Clark * Arlington Va Rush Medical College, Chicago, 1881, an Affiliate Fellow of the American Medical Association, member of the Minnesota State Medical Association, for many years member of the Minnesota National Guard, veteran of the Spanish-American War formerly on the staff of the Minnesota Soldiers Home, Minneapolis aged 89, died June 19, in Washington, D C, of cerebral hemorrhage and arteriosclerosis

William Everett Gray, Milltown N B Canada McGill University Faculty of Medicine, Montreal, Que, 1907 member of the New England Obstetrical and Gynecological Society, past president of the New Brunswick Medical Society, on the

staff of the Chipman Memorial Hospital St Stephen where he organized and served as pathologist in the Prescott Memorial Laboratories, aged 56 died, May 22

Henry William George * Middletown Pa Jefferson Medical College of Philadelphia 1901 member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology Inc specialist certified by the American Board of Ophthalmology for many years president of the local school board aged 64, died July 7 in the Jefferson Hospital Philadelphia

Evan Griffith Galbraith * Toledo Ohio, University of Michigan Medical School, Ann Arbor 1916, specialist certified by the American Board of Otolaryngology member of the American Broncho-Esophagological Association served during World War I, aged 54 was killed, June 14, when the automobile in which he was driving was struck by a tram near Devils Lake, Mich

George Walter Brasher * Jackson Tenn University of Tennessee Medical Department, Nashville 1909 past president of the Madison County Medical Society and the West Tennessee Medical Association councilor of the Eighth District Medical Society, aged 70, died, June 25, in the Fitts-White Clinic of coronary thrombosis

Harold Flavell Westcott, Clayton, N Y Jefferson Medical College of Philadelphia, 1916 member of the Medical Society of the State of New York, served in the medical corps of the U S Army during World War I health officer and school physician of Clayton, aged 47, died June 25, in Blackwood, N J, of coronary thrombosis

David Feiner * Brooklyn, University and Bellevue Hospital Medical College New York, 1912 specialist certified by the American Board of Obstetrics and Gynecology Inc on the staffs of the Adelpi and Israel-Zion hospitals aged 52 was killed, June 15 when he fell from a sixth floor roof

Dwight Cortland Phillips * Chicago College of Physicians and Surgeons of Chicago 1895 served as a captain with the American Expeditionary Forces in France during World War I, for many years on the staff of St Mary of Nazareth Hospital, aged 69, died, June 15, of heart disease

George Warren Newell, Burlington Wis Northwestern University Medical School, Chicago, 1905 city health officer, served as a major in the medical corps of the U S Army in France during World War I, aged 64, died June 29, in Rochester Minn, of carcinoma of the prostate

William Taylor Lindsay, Moscow Ohio, Starling Medical College, Columbus, 1893, for many years Hamilton County jail physician, at one time district physician for the board of health of Cincinnati, aged 74, died June 14, of carcinoma of the pancreas with metastasis to the liver

John Joseph Mahoney, Los Angeles, Beaumont Hospital Medical College St Louis, 1901, St Louis University School of Medicine, 1905, for many years a member of the city health department, aged 71, died, June 4 in St Vincent's Hospital of heart disease and arteriosclerosis

Clyde Vincent Nelson Jr, Van Nuys Calif University of Southern California School of Medicine Los Angeles 1935, member of the California Medical Association aged 31 was killed, June 19 when he fell down the icy slope of the Grand Teton Mountain in Wyoming

Henry Percival Hargrave, Medford Ore Manitoba Medical College Winnipeg, Man Canada 1895 formerly health officer of Jackson County and member of the city council of Medford aged 67 died June 28 of cerebral hemorrhage and carcinoma of the bladder

Ferdinand Rosenberger * New York Ludwig Maximilians-Universität Medizinische Fakultät München Paderborn Germany, 1917 aged 50, on the staffs of the Hospital for Joint Diseases and the Mount Sinai Hospital, where he died June 2, of coronary thrombosis

Alvis A Williamson, Michigantown Ind, Medical College of Indiana Indianapolis 1898 member of the Indiana State Medical Association president of the Clinton County Medical Society aged 68 died June 28, of diabetes mellitus

Albert H Wales, Santa Monica Calif Chicago Homeopathic Medical College 1888 Harvey Medical College Chicago 1896 served during World War I aged 75 died, May 19, of cerebral thrombosis and prostatic hypertrophy

Fred Carl Weber * Newport Ky Pulaski Medical College Cincinnati 1904 member of the board of education served in France during World War I formerly mayor of Newport, aged 64 died, July 11, of cerebral hemorrhage

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," or medical devices have agreed with the Federal Trade Commission to discontinue certain misrepresentations in their advertising. These stipulations differ from the 'Cease and Desist Orders' of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Bullock's Products—Henry Sprangler using the trade styles National Laboratories and National Laboratories Inc. Benjamin Franklin Station Washington D. C. stipulated with the Federal Trade Commission in October 1941 that he would discontinue the following misrepresentations in his advertising: that Bullock's System or the preparations designated as Bullock's Antiseptic Healing and Cleansing Tonic, Bullock's Nasal Salve, Bullock's Anti-epileptic Emollient and Bullock's Clear Head Tablets or any other preparation of substantially the same composition as the foregoing constitutes a competent remedy for sinusitis, infectious catarrh or any other disorder of the nose, mouth, throat or sinus. He further agreed that he would either discontinue any advertisements which failed to reveal that the frequent or continued use of Bullock's Clear Head Tablets or any similar preparation may be dangerous causing collapse or dependence on the drug or include in his advertisements the warning that his product should be used only as directed on the label and that the label itself would warn the user that the frequent or continued taking of the product might be dangerous causing collapse or dependence on the drug.

Calafol Liquid—In December 1941 the Calafol Company Inc. Los Angeles signed a stipulation with the Federal Trade Commission regarding Calafol Liquid. In this it agreed to cease representing the product as being capable of checking the tendency toward attacks of asthma and hay fever and to discontinue any advertisements which failed to reveal that the nostrum should not be used by persons suffering from lung disease, chronic cough, goiter or thyroid disease except on advice from a physician. There also was to be given the warning that its use should be discontinued if a skin rash appeared and also that its use over an extended period should be avoided except on competent medical advice in addition to the warning that it should not be given to children. The stipulation however provided that if the label carried sufficient warning as to the foregoing the advertisements need contain only the statement: Caution use only as directed. Calafol Liquid was reported by government chemists to be essentially a mixture of potassium iodide, opium, alcohol and water back in 1934 when it was declared in a federal court to bear false and fraudulent claims on its label.

George Gary Earnist 'Health Booklets'—From New York Bernard Munves, Paul Pukuh and Benjamin Pukuh operating under the name George Gary Earnist sold booklets designated 'The Daily Five' and 'The Hundred Dollar System of Scientific Physical Efficiency'. These contained instructions for certain physical exercises as well as a 'Daily Diet' and other alleged health rules and suggestions. In October 1941 these three persons signed a stipulation with the Federal Trade Commission in which they agreed to discontinue misrepresentations in the advertising of their booklets. Among these were that the exercises outlined in these booklets will have any demonstrable effect on or are a competent remedy for indigestion, torpid liver, nervous trouble, impure blood or weak heart or lungs; that such exercises can be depended on to remove constipation or its cause; to correct ill health, preserve health or strength or revitalize the system; or that by following exercise instructions as outlined, internal organs not under voluntary control will be exercised. According to the stipulation the respondents also will cease representing that the 'Daily Diet' as set forth in the booklets contains complete dietary information and hygienic rules or that such 'Diet' is in accordance with the modern science of dietetics; that the 'Shockless Cold Bath' described in the booklets is or acts as a nerve tonic or has any beneficial effect on the brain or nerve center; and representing or quoting as the customary or regular price or value of the booklets prices or values which are in fact fictitious and in excess of the prices at which the booklets customarily are offered for sale and sold in the normal course of business. According to the Bureau of Investigation's files, George Gary Earnist was the originator of 'The Daily Five'. The *West Virginia Medical Journal* for January 1938 called attention to the fact that in promoting his course, Earnist had used a photostat of a testimonial written on the stationery of the West Virginia State Medical Association by one of their counselors. This man had served the Association in 1911 and had long since died. Above the letter Earnist had played up the claim 'Medical Association Recommends The Daily Five' which because of the individual signature and the date of the letter was obviously misleading.

Hayrin Nasal Filters—This is put out by Medical Products Institute, Inc., Cincinnati. In July 1941 that concern stipulated with the Federal Trade Commission that it would cease representing that its device will prevent or cure or constitute a treatment for hay fever, rose fever or seasonal asthma; that this mechanism when used in combination with a

filter pad impregnated with Hayrin Nasal Filter Pad Fluid will overcome the symptoms due to pollens and molds which might enter the body; that its filters purify or completely filter the air breathed or prevent pollens or molds from reaching the sensitive membranes or aid in the treatment or prevention of colds. Further, the concern promised to cease representing itself as an institute devoted to scientific study of ailments and conditions of the body.

H V 222—This is a product of H V Laboratories Inc., St. Louis which in December 1941 stipulated with the Federal Trade Commission to discontinue the following misrepresentations in the advertising that this preparation is a remedy or cure for skin eruptions or irritation including rash or eczema or has any value in treating them beyond giving relief to the associated itching; that it will cure or prevent athlete's foot or will penetrate or kill such of the fungi of this condition as may develop beneath the cornuous layer of the unbroken skin or that in treating this disorder it has any beneficial effect on the tissues deeper than the peripheral vascular system beneath an unbroken skin; that it will remove the blisters manifesting the condition known as athlete's foot or that diluted or undiluted it kills the germ infection or fungi of athlete's foot in 30 seconds or in any other definitely stated period of time. The concern further agreed to cease representing that H V 222 is a preventer or prevents or stops bleeding or craves coagulation.

Knipe Shoes—The concern put out by Knipe Brothers Inc., shoe manufacturers of Ward Hill, Mass. In December 1941 that concern signed a stipulation with the Federal Trade Commission in which it agreed to cease using the word 'Doctor' or the term 'Dr.' or any simulation thereof as a trade name for the shoes that it sells which term might give the impression that the shoes so designated are made in accordance with the design or under the supervision of a physician and contain special scientific or orthopedic features which are the result of medical determination or services.

Luvos Pack and Luvos Minerals—These were sold by a Paul R. Kemper trading as Luvos (My Company of America) and as Luvos Minerals Company, Los Angeles. In a stipulation that Kemper signed with the Federal Trade Commission in September 1941 he agreed to discontinue these misrepresentations: that Luvos Pack is a remedy or cure for a mouth or throat ailment, rheumatic neuralgia or other disorders or offers any benefit beyond that of its poultice-like action in temporarily relieving pain; that Luvos Minerals will prevent or remedy colitis, gastritis, hyperacidity and numerous other conditions or do more than aid in reducing hyperacidity or be of any value in the treatment of throat irritations or infection. Kemper further agreed to cease representing that either of the products is free from drugs or medication or prescribed by physicians or that Luvos Minerals has any influence on metabolism or will bind poisonous material or react on the whole body organism.

Miel de Maquey, Germ of Wheat, Red Meal, Kefement and Melvite Food—These were represented as health foods by Solomon Sherman trading as Sherman Foods, New York. In November 1941 this person stipulated with the Federal Trade Commission that he would cease representing among other things that Miel de Maquey is valuable as a preventive of rickets or is superior in nutritive and vitamin value to cod liver oil or is a substitute therefor; that Germ of Wheat will build resistance and can be depended on to combat constipation and digestion; improve the appetite or cruse steady nerves; that Red Meal constitutes a complete food or that Kefement one of its ingredients is an important dietary element; that Kefement is a competent treatment for goiter, kidney disease, low vitality, neuritis, overweight, rheumatism and other ailments; and that Melvite Food is a superior source of energy.

M K—Mantho Kreoamo—This nostrum is put out by Mantho Kreoamo Inc., Clinton, Ill. Both in the name of the nostrum and of the company, Mantho was originally written Mentho. Although this latter term suggested that the product was based on menthol, only a trace of that substance was found by government chemists who tested a specimen of the preparation back in 1928. They stated that in addition to the menthol, the product consisted essentially of ammonium chloride, wood tar, creosote, sugar and water. The government charged that the product, Mentho Kreoamo, was fraudulently represented as a remedy for bronchial troubles. Just when the name was changed is not apparent, but the records show that in July 1936 Mantho Kreoamo Inc. stipulated with the Federal Trade Commission that it would no longer represent that 'M K Cold Remedy' (presumably another title for Mantho Kreoamo) prevents pneumonia and is effective for coughs, colds, bronchitis or complications of colds unless such representations are limited to symptomatic relief. In a second stipulation which the concern signed with the Federal Trade Commission in October 1941 it agreed to discontinue the following misrepresentations in the advertising of M K—Mantho Kreoamo: that the product will combat symptoms of cold infections; prevent colds; soothe inflamed bronchial membranes; allay fever or give relief in cases of influenza or bad colds in excess of such relief as its expectorant properties might offer. The concern also agreed to cease representing that the person from whose prescription the formula originated or was developed was a noted Illinois physician or had national fame.

Na Pa Balm—This is put out by D. R. Sterett and Margaret Sterett trading under the name Na Pa Chemical Company, Leavenworth, Kan. In January 1941 the Steretts signed a stipulation with the Federal Trade Commission in which they agreed to discontinue the following misrepresentations in advertising this nostrum: that it is a competent treatment or an effective remedy for colds; will break up colds or provide protection against them or offer more than temporary relief from the symptoms and discomforts associated therewith; that Na Pa Balm is a remedy for will protect against or aid in the prevention of muscular aches and minor ailments or afford more than temporary relief from such painful conditions; that it penetrates keeps out cold germs or

service as a remedy for or preventive of throat infections or sinus irritations. The Steretts further agreed that in making comparisons of the absorbability of goose grease or any other ingredient in their product they will state the ingredient with which comparison is made and further will not go beyond the facts.

Olbas Herb Oil—R. Keller of New York trading as Olbas Company stipulated with the Federal Trade Commission in August 1941 that he would no longer represent that this product will ease the spasms of coughing asthma or irritation of the respiratory channels or relieve flatulence or digestive disturbances that the essential oil from which Olbas is distilled is scarcely known in the Western world and that every detail of Olbas's varied application is supported by clinical evidence from European physicians.

Rhumo Tabs Rhumo Rub Healo Salv and At Letes Foot Liquid Balm—These are put out by a Harry Florian trading as Florian Drug Company Chicago. In a stipulation that he signed with the Federal Trade Commission in December 1941 he agreed to discontinue the following misrepresentations in his advertising that Rhumo Tabs is a new discovery in the treatment of rheumatism that Rhumo Rub is an effective remedy for colds or superior in effectiveness and rapidity of action to all competitive products that Healo Salv heals or aids in the healing of ulcers boils or similar ailments or in conditions considered incurable or that At Letes Foot Liquid Balm is a cure for scabies or barber's itch. Further he agreed to discontinue use of the word Healo to designate or describe the product sold as Healo Salv or from otherwise representing that it is a cure or remedy.

"Short Stature and Height Increase"—This was the title of a book promoted by one Benjamin H. Levine trading as Harvest House New York. According to a stipulation that he signed with the Federal Trade Commission in December 1941 he agreed to cease representing that this volume outlines methods for increasing height by growth or through use of terms such as medically approved that the methods presented in the book for increasing one's appearance of height have been approved by a medical group association or society.

Slendotabs—That the use of these tablets is an easy dependable sensible or correctly balanced weight reducing method or will attractively or otherwise effectively slenderize the user's figure or that physicians would approve of it as a competent and safe means of permanent weight reduction were misrepresentations which Caylord W. Keeton Arthur Nebel and Frank Sterling trading as Keneco Health Products Elmira, N. Y. agreed to discontinue in a stipulation that they signed with the Federal Trade Commission in December 1941.

Stop—This is put out by an H. G. Bernstein trading as Purity Certified Products Chicago. In November 1941 Bernstein stipulated with the Federal Trade Commission that he would discontinue certain misrepresentations. Among them were that Stop purifies the breath or kills or neutralizes unpleasant breath odors or that it possesses efficiency as a deodorant except to the extent that it may partially and temporarily mask unpleasant breath odors. Bernstein further stipulated that he would cease using the name Stop or any other designation which implies that the product stops bad breath.

Stop Lite Products—These consisted of 'Stop Lites Haps' and 'Anti Acid Tablets' all put out by Stop Lite Products, Inc. of Salt Lake City. In August 1941 this concern stipulated with the Federal Trade Commission to discontinue the following misrepresentations that Stop Lites (a tablet) will relieve or cure a cold or will benefit that condition any way beyond inducing laxation and affording temporary relief from the physical discomfort of the symptoms that it is different from any other product intended for the same purpose or constitutes an effective internal antiseptic or is safe to use or that the Anti Acid Tablets aid digestion. The concern further agreed to discontinue any advertisements for Stop Lites or Haps which failed to reveal that frequent or continued use of either of these may be dangerous causing serious blood disturbances and that the product should not be administered in excess of the dosage recommended. The stipulation provided however that when the labels of these products contained a similar warning the advertisements need only caution the reader that either preparation should be used only as directed on the label. In October 1941 W. E. Featherstone trading as W. E. Featherstone Advertising Agency Salt Lake City signed a similar stipulation.

Thelorysus—In a stipulation signed with the Federal Trade Commission in September 1941 Fred E. Thieleman trading as Thieleman Drug Company Dearborn, Mich. agreed to cease representing that this product has any value in the treatment of eczema pimples itch or other skin disorders or that it is an elixir which will stimulate general systemic resistance to psoriasis or resolve and abate persistent lesions.

Vitamina and Vitaminscope—The first named product was said to be an oil extracted from sharks' livers and the second a device for determining vitamin A deficiency. They were put out by a Carlton Deederer M. D. of Miami, Fla. trading as Dr. Deederer Products. In a stipulation that he signed with the Federal Trade Commission in August 1941 he agreed to cease representing among other things that 'Vitamina' will in any manner benefit the health of users except to the extent that it may benefit the health of those who suffer from a vitamin A deficiency that it will benefit the average diet by supplying a vitamin A deficiency that it is a super vitamin or in any way superior to the vitamin A obtained from other sources that it will prevent or dissolve calcium deposits in the system eliminate or prevent gray hair or baldness or make hair grow. Further Dr. Deederer stipulated that he would cease representing that the Vitaminscope will accurately show the extent to which a vitamin A deficiency exists in any given case or the extent to which such deficiency is being supplied by administration of any source of vitamin A or that the device will standardize the amount of vitamin A in the preparation Vitamina.

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D. D. N. J. and foods, F. N. J. The abstracts that follow are given in the briefest possible form: (1) the name of the product (2) the name of the manufacturer, shipper or consigner (3) the date of shipment (4) the composition (5) the type of nostrum (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Parkelp and Parkelp Tablets—Philip R. Park, Inc. San Pedro, Calif. Aug. 2, 1940. Composition: Parkelp dried kelp (seaweed). Parkelp Tablets same material compressed into tablet form. Charge of misbranding was based on false label representations that these products were an effective treatment for hair and scalp troubles, secondary rheumatism, rickets and other types of bone deficiency and would supply adequate amounts of mineral to the diet thus relieving many disorders such as colds, rheumatism, heart trouble, goiter and eczema.—[D. D. N. J. F. D. C. 388 March 1942.]

Pronto—Alfred S. Hooper, Los Angeles, May 9, 1940. Composition: powders each containing bismuth subcarbonate 9.15 grains, magnesium oxide 4.22 grains, aspirin (free and combined) 3.6 grains, a substance such as kaolin and sugar. Falsely represented as an effective treatment of stomach and bowel ailments including colitis and ulcers.—[D. D. N. J. F. D. C. 389 March 1942.]

Red Fox Quinine Hair Tonic—Herlox Company, Inc. Brooklyn, N.Y. 12, 1940. Composition: essentially alcohol, water and small amounts of brucine and perfume. Misbranded because no quinine was present although so represented in the name, also because the claim that dandruff was false.—[D. D. N. J. F. D. C. 362 March 1942.]

Ro-Mari—American Ru-Mari Company, Los Angeles. Between Feb. 17 and April 1, 1940. Composition: about 99 per cent water with minute amounts of potassium carbonate, sodium hydroxide, chloride, sulfate and carbonate and a trace of an organic compound such as chloramine T. Misbranded because the word Ru-Mari in the firm's name falsely represented that its product was a remedy for rheumatism, further misbranded because of label representations that it possessed effective diuretic action in treating arthritis, neuritis, sciatica, lumbago, gout and allied conditions, would promote elimination of toxin-forming matter through the urinary tract and was a blood conditioner.—[D. D. N. J. F. D. C. 390 March 1942.]

St. Bernard Compound Herb Tonic—Dr. J. Lynch A. Johnson, Memphis, Tenn. Between Jan. 4 and Jan. 16, 1940. Composition: essentially plant materials such as saffron bark, marjoram, mallow flowers and buchu leaves. Misbranded because label falsely claimed it to be a cure for irritation of the kidneys, bladder, gravel, backache and certain rheumatic disorders, besides being a tonic and antispasmodic.—[D. D. N. J. F. D. C. 369 March 1942.]

Sun Dried Nova Scotia Dulce—Gus E. Sjoberg trading as Coffin Fish Company, Seattle. Between Aug. 23 and Dec. 27, 1939. Composition: a dark brown vegetable material apparently dried seaweed. Misbranded because falsely represented on cartons and in circulars as efficacious for treating goiter, constipation, scurvy, thyroid disturbances, stomach troubles and some other things.—[D. D. N. J. F. D. C. 374 March 1942.]

Wonder Dandruff Cure—Wonder Dandruff Cure Company, Cedar Rapids, Iowa. Aug. 3, 1940. Composition: an artificially colored perfumed watery solution containing arsenic, alcohol and glycerin. Misbranded because falsely claimed on the label to eradicate dandruff, restore lifeless hair to a healthy natural condition, prevent it from coming out and stop irritation and itching of the scalp, further misbranded because label did not bear the common name of each active ingredient or an accurate statement of the amounts of alcohol and arsenic present.—[D. D. N. J. F. D. C. 363 March 1942.]

World Famous New Life Laxative Tonic—Harry B. Kohn trading as New Life Medicine Company, Atlanta, Ga. Between Oct. 2 and Dec. 7, 1939. Composition: opium salt free sulfur,enna and other horceice and unidentified material. Misbranded because falsely represented to improve health, cleanse the system, act as a tonic and be an effective treatment for a long list of disorders. Defendant found guilty and placed on probation for one year.—[D. D. N. J. F. D. C. 375 March 1942.]

World's Tonic Compound with Alkalines—World's Medicine Company, Columbus, Ohio. July 6, 1940. Composition: essentially plant drugs including saffron bark, horceice and laxatives such as aloin and crotonol, ing drug together with 12 per cent of alcohol and small amounts of iron, strychnine and alkaline substances. Misbranded because it is essentially a laxative, it was falsely represented as a tonic and a source of alkalis. Further misbranded because various contents were incorrectly declared.—[D. D. N. J. F. D. C. 361 March 1942.]

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of 'patent medicines,' or medical devices have agreed with the Federal Trade Commission to discontinue certain misrepresentations in their advertising. These stipulations differ from the 'Cease and Desist Orders' of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Bullock's Products—Henry Sprangler, using the trade styles National Laboratories and National Laboratories, Inc., Benjamin Franklin Station, Washington, D. C., stipulated with the Federal Trade Commission in October 1941 that he would discontinue the following misrepresentations in his advertising: that Bullock's System or the preparations designated as Bullock's Antiseptic Healing and Cleansing Tonic, Bullock's Nasal Salve, Bullock's Antiseptic Emollient, and Bullock's Clear Head Tablets, or any other preparation of substantially the same composition as the foregoing constitutes a competent remedy for sinusitis, infectious catarrh, or any other disorder of the nose, mouth, throat, or sinus. He further agreed that he would either discontinue any advertisements which failed to reveal that the frequent or continued use of Bullock's Clear Head Tablets or any similar preparation may be dangerous, causing collapse or dependence on the drug, or include in his advertisements the warning that his product should be used only as directed on the label and that the label itself would warn the user that the frequent or continued taking of the product might be dangerous, causing collapse or dependence on the drug.

Calafé Liquid—In December 1941 the Calafé Company, Inc., Los Angeles, signed a stipulation with the Federal Trade Commission regarding Calafé Liquid. In this it agreed to cease representing the product as being capable of checking the tendency toward attacks of asthma and hay fever and to discontinue any advertisements which failed to reveal that the nostrum should not be used by persons suffering from lung disease, chronic cough, goiter, or thyroid disease except on advice from a physician. There also was to be given the warning that its use should be discontinued if a skin rash appeared and also that its use over an extended period should be avoided except on competent medical advice in addition to the warning that it should not be given to children. The stipulation, however, provided that if the label carried sufficient warning as to the foregoing the advertisements need contain only the statement: Caution: Use only as directed. Calafé Liquid was reported by government chemists to be essentially a mixture of potassium iodide, opium, alcohol, and water back in 1934 when it was declared in a federal court to bear false and fraudulent claims on its label.

George Cary Earnst "Health Booklets"—From New York, Bernard Munves, Paul Pukuli, and Benjamin Pukuli, operating under the name George Cary Earnst, sold booklets designated "The Daily Five" and "The Hundred Dollar System of Scientific Physical Efficiency." These contained instructions for certain physical exercises as well as a Daily Diet and other alleged health rules and suggestions. In October 1941 these three persons signed a stipulation with the Federal Trade Commission in which they agreed to discontinue misrepresentations in the advertising of their booklets. Among these were that the exercises outlined in these booklets will have any demonstrable effect on or are a competent remedy for indigestion, torpid liver, nervous trouble, impure blood, or weak heart or lungs; that such exercises can be depended on to remove constipation or its cause, to correct ill health, preserve health, or strength, or revitalize the system; or that by following exercise instructions as outlined, internal organs not under voluntary control will be exercised. According to the stipulation, the respondents also will cease representing that the Daily Diet, as set forth in the booklets, contains complete dietary information and hygienic rules, or that such Diet is in accordance with the modern science of dietetics, that the "Shockless Cold Bath" described in the booklets is or acts as a nerve tonic, or has any beneficial effect on the brain or nerve center, and representing or quoting as the customary or regular price or value of the booklets prices or values which are in fact fictitious and in excess of the prices at which the booklets customarily are offered for sale and sold in the normal course of business. According to the Bureau of Investigation's files, George Cary Earnst was the originator of The Daily Five. The *West Virginia Medical Journal* for January 1938 called attention to the fact that in promoting his course, Earnst had used a photostat of a testimonial written on the stationery of the West Virginia State Medical Association by one of their councilors. This man had served the Association in 1911 and had long since died. Above the letter, Earnst had played up the claim "Medical Association Recommends The Daily Five," which because of the individual signature and the date of the letter was obviously misleading.

Hayrin Nasal Filters—This is put out by Medical Products Institute, Inc., Cincinnati. In July 1941 that concern stipulated with the Federal Trade Commission that it would cease representing that its device will prevent or cure or constitute a treatment for hay fever, rose fever, or seasonal asthma, that this mechanism, when used in combination with a

filter pad impregnated with Hayrin Nasal Filter Pad Fluid, will overcome the symptoms due to pollen and molds which might enter the body, that its filters purify or completely filter the air breathed or prevent pollen or molds from reaching the sensitive membranes or aid in the treatment or prevention of colds. Further, the concern promised to cease representing itself as an institute devoted to scientific study of ailments and conditions of the body.

H. V. 222—This is a product of H. V. Laboratories, Inc., St. Louis, which in December 1941 stipulated with the Federal Trade Commission to discontinue the following misrepresentations in the advertising: that this preparation is a remedy or cure for skin eruptions or irritation, including rash or eczema, or has any value in treating them beyond giving relief to the associated itching; that it will cure or prevent athlete's foot, will penetrate or kill such of the fungi in this condition as may develop beneath the corns layer of the unbroken skin, or that in treating this disorder it has any beneficial effect on the tissues deeper than the peripheral vascular system beneath an unbroken skin; that it will remove the blisters manifesting the condition known as athlete's foot or that diluted or undiluted it kills the germ infection or fungi of athlete's foot in 30 seconds or in any other definitely stated period of time. The concern further agreed to cease representing that H. V. 222 is a preservative or prevents or stops bleeding, or causes coagulation.

Knipe Shoes—These are put out by Knipe Brothers, Inc., shoe manufacturers of Ward Hill, Mass. In December 1941 that concern signed a stipulation with the Federal Trade Commission in which it agreed to cease using the word Doctor or the term Dr. or any simulation thereof as a trade name for the shoes that it sells, which term might give the impression that the shoes so designated are made in accordance with the design or under the supervision of a physician and contain special scientific or orthopedic features which are the result of medical determination or advice.

Luvos Pack and Luvos Minerals—These were sold by a Paul R. Kemper, trading as Luvos (by) Company of America and as Luvos Minerals Company, Los Angeles. In a stipulation that Kemper signed with the Federal Trade Commission in September 1941 he agreed to discontinue the misrepresentations that Luvos Pack is a remedy or cure for mouth or throat ailments, rheumatic neuralgia, or other disorders, or offers any benefit beyond that of its purgative-like action in temporarily relieving pain; that Luvos Minerals will prevent or remedy colitis, gastritis, hyperacidity, and numerous other conditions, or do more than aid in reducing hyperacidity or be of any value in the treatment of throat irritations or infection. Kemper further agreed to cease representing that either of the products is free from drugs or medication or prescribed by physicians, or that Luvos Minerals has any influence on metabolism or will bind poisonous material or react on the whole body organism.

Miel de Magney, Germ of Wheat, Red Meal, Kelement, and Melvite Food—These were represented as health foods by Solomon Sherman, trading as Sherman Food, New York. In November 1941 this person stipulated with the Federal Trade Commission that he would cease representing, among other things, that Miel de Magney is valuable as a preventive of rickets, or is superior in nutritive and vitamin value to cod liver oil, or is a substitute therefor; that Germ of Wheat will build resistance and can be depended on to combat constipation and digestion, improve the appetite, or cure steady nerves; that Red Meal constitutes a complete food, or that Kelement, one of its ingredients, is an important dietary element; that Kelement is a competent treatment for gonorrhea, skin diseases, low vitality, neuritis, overweight, rheumatism, and other ailments; and that Melvite Food is a superior source of energy.

M. K.—Mantho Kreoamo—This nostrum is put out by Mantho Kreoamo, Inc., Clinton, Ill. Both in the name of the nostrum and of the company, Mantho was originally written, Mentho. Although this latter term suggested that the product was based on menthol, only a trace of that substance was found by government chemists who tested a specimen of the preparation back in 1928. They stated that in addition to the menthol, the product consisted essentially of ammonium chloride, wood tar, croscote sugar, and water. The government charged that the product, Mantho Kreoamo, was fraudulently represented as a remedy for bronchial troubles. Just when the name was changed is not apparent, but the records show that in July 1936 Mantho Kreoamo, Inc. stipulated with the Federal Trade Commission that it would no longer represent that M. K. Cold Remedy (presumably another title for Mantho Kreoamo) prevents pneumonia and is effective for coughs, colds, bronchitis, or complications of colds, unless such representations are limited to symptomatic relief. In a second stipulation, which the concern signed with the Federal Trade Commission in October 1941, it agreed to discontinue the following misrepresentations in the advertising of M. K.—Mantho Kreoamo: that the product will combat symptoms of cold infections, prevent colds, soothe inflamed bronchial membranes, allay fever, or give relief in cases of influenza or bad colds in excess of such relief as its expectorant properties might offer. The concern also agreed to cease representing that the person from whose prescription the formula originated or was developed was a noted Illinois physician or had national fame.

Na Pa Balm—This is put out by D. R. Sterett and Margaret Sterett, trading under the name Na Pa Chemical Company, Leavenworth, Kan. In January 1941 the Steretts signed a stipulation with the Federal Trade Commission in which they agreed to discontinue the following misrepresentations in advertising this nostrum: that it is a competent treatment or an effective remedy for colds, will break up colds or provide protection against them or offer more than temporary relief from the symptoms and discomforts associated therewith; that Na Pa Balm is a remedy for will protect against or aid in the prevention of muscular aches and minor ailments or afford more than temporary relief from such painful conditions; that it penetrates, keeps out cold germs, or

services as a remedy for or preventive of throat infections or sinus irritations. The Steretts further agreed that in making comparisons of the absorbability of goose grease or any other ingredient in their product they will state the ingredient with which comparison is made and further will not go beyond the facts.

Olbas Herb Oil—R. Keller of New York trading as Olbas Company stipulated with the Federal Trade Commission in August 1941 that he would no longer represent that this product will ease the spasms of coughing asthma or irritation of the respiratory channels or relieve flatulence or digestive disturbances that the essential oil from which Olbas is distilled is scarcely known in the Western world and that every detail of Olbas's varied application is supported by clinical evidence from European physicians.

Rhmo Tabs Rhmo Rub Healo Salv and At Letes Foot Liquid Balm—These are put out by a Harry Florian trading as Florian Drug Company Chicago. In a stipulation that he signed with the Federal Trade Commission in December 1941 he agreed to discontinue the following misrepresentations in his advertising that Rhmo Tabs is a new discovery in the treatment of rheumatism that Rhmo Rub is an effective remedy for colds or superior in effectiveness and rapidity of action to all competitive products that Healo Salv heals or aids in the healing of ulcers, boils or similar ailments or in conditions considered incurable, or that At Letes Foot Liquid Balm is a cure for scabies or barber's itch. Further he agreed to discontinue use of the word 'Healo' to designate or describe the product sold as Healo Salv or from otherwise representing that it is a cure or remedy.

"Short Stature and Height Increase"—This was the title of a book promoted by one Benjamin H. Levine trading as Harvest House New York. According to a stipulation that he signed with the Federal Trade Commission in December 1941 he agreed to cease representing that this volume outlines methods for increasing height by growth or through use of terms such as 'medically approved' that the methods presented in the book for increasing one's appearance of height have been approved by a medical group association or society.

Slendotabs—That the use of these tablets is an easy dependable sensible or correctly balanced weight reducing method or will attractively or otherwise effectively slenderize the user's figure or that physicians would approve of it as a competent and safe means of permanent weight reduction were misrepresentations which Cloyd W. Keeton, Arthur Nebel and Frank Sterling trading as Keneco Health Products Elmhurst, N. Y., agreed to discontinue in a stipulation that they signed with the Federal Trade Commission in December 1941.

Stop—This is put out by an H. G. Bernstein trading as Purity Certified Products Chicago. In November 1941 Bernstein stipulated with the Federal Trade Commission that he would discontinue certain misrepresentations. Among them were that Stop purifies the breath or kills or neutralizes unpleasant breath odors or that it possesses efficacy as a deodorant except to the extent that it may partially and temporarily mask unpleasant breath odors. Bernstein further stipulated that he would cease using the name 'Stop' or any other designation which implies that the product stops bad breath.

Stop Lite Products—These consisted of Stop Lites Haps and Anti Acid Tablets, all put out by Stop Lite Products Inc. of Salt Lake City. In August 1941 this concern stipulated with the Federal Trade Commission to discontinue the following misrepresentations that Stop Lites (a tablet) will relieve or cure a cold or will benefit that condition any way beyond inducing laxation and affording temporary relief from the physical discomfort of the symptoms that it is different from any other product intended for the same purpose or constitutes an effective internal antiseptic or is safe to use or that the Anti Acid Tablets aid digestion. The concern further agreed to discontinue any advertisements for Stop Lites or Haps which failed to reveal that frequent or continued use of either of these may be dangerous causing serious blood disturbances and that the product should not be administered in excess of the dosage recommended. The stipulation provided however that when the labels of these products contained a similar warning the advertisements need only caution the reader that either preparation should be used only as directed on the label. In October 1941 W. E. Featherstone trading as W. E. Featherstone Advertising Agency Salt Lake City signed a similar stipulation.

Thelorysus—In a stipulation signed with the Federal Trade Commission in September 1941 Fred E. Thieleman trading as Thieleman Drug Company Dearborn, Mich., agreed to cease representing that this product has any value in the treatment of eczema, pimples, itch or other skin disorders or that it is an elixir which will stimulate general systemic resistance to psoriasis or resolve and abate persistent lesions.

Vitamina and Vitaminascope—The first named product was said to be an oil extracted from sharks' livers and the second a device for determining vitamin A deficiency. They were put out by a Carlton Deederer, M. D. of Miami, Fla., trading as Dr. Deederer Products. In a stipulation that he signed with the Federal Trade Commission in August 1941 he agreed to cease representing among other things that Vitamina will in any manner benefit the health of users except to the extent that it may benefit the health of those who suffer from a vitamin A deficiency, that it will benefit the average diet by supplying a vitamin A deficiency, that it is a super-vitamin or in any way superior to the vitamin A obtained from other sources that it will prevent or dissolve calcium deposits in the system eliminate or prevent gray hair or baldness or make hair grow. Further Dr. Deederer stipulated that he would cease representing that the Vitaminascope will accurately show the extent to which a vitamin A deficiency exists in any given case or the extent to which such deficiency is being supplied by administration of any source of vitamin A or that the device will standardize the amount of vitamin A in the preparation Vitamina.

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D D N J and foods, F N J. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consignor, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Parkelp and Parkelp Tablets—Philip R. Park, Inc., San Pedro, Calif., Aug. 2, 1940. Composition: Parkelp dried kelp (seaweed). Parkelp Tablets same material compressed into tablet form. Charge of misbranding was based on false label representations that these products were an effective treatment for hair and scalp troubles, secondary anemia, rickets and other types of bone deficiency and would supply adequate amounts of mineral to the diet, thus relieving many disorders such as colds, anemia, obesity, heart trouble, goiter and eczema.—[D D N J F D C 388 March 1942]

Pronto—Alfred S. Hope, Los Angeles, May 8, 1940. Composition: powders each containing bismuth subcarbonate 9.15 grains, magnesium oxide 4.22 grains, aspirin (free and combined) 3.6 grains and silicates such as kaolin and sugar. Falsely represented as an effective treatment of stomach and bowel ailments including colitis and ulcers.—[D D N J F D C 389 March 1942]

Red Fox Quinine Hair Tonic—Healox Company, Inc., Brooklyn, Nov. 12, 1940. Composition: essentially alcohol, water and small amounts of brucine and perfume. Misbranded because no quinine was present although so represented in the name also because the claim relieves dandruff was false.—[D D N J F D C 367 March 1942]

Ro Mari—American Ru Mari Company, Los Angeles, Between Feb. 17 and April 1, 1940. Composition: about 99 per cent water with minute amounts of potassium carbonate, sodium hydroxide, chloride, sulfate and carbonate and a trace of an organic compound such as chloramine T. Misbranded because the word 'Ru Mari' in the firm's name falsely represented that its product was a remedy for rheumatism further misbranded because of label representations that it possessed effective diuretic action in treating arthritis, neuritis, sciatica, lumbago, gout and allied conditions, would promote elimination of toxin forming matter through the urinary tract and was a blood conditioner.—[D D N J F D C 390 March 1942]

St. Bernard Compound Herb Tea—Dr. Lyncha A. Johnson, Memphis, Tenn., Between Jan. 4 and Jan. 16, 1940. Composition: essentially plant materials such as sassafras bark, uva ursi, mallow flowers and buchu leaves. Misbranded because label falsely claimed it to be useful for irritation of the kidneys, bladder, gravel, headache and certain rheumatic disorders besides being a tonic and antispasmodic.—[D D N J F D C 369 March 1942]

Sun Dried Nova Scotia Dulse—Gus E. Sjoberg trading as Coffin Fish Company, Seattle, Between Aug. 23 and Dec. 27, 1939. Composition: a dark brown vegetable material apparently dried seaweed. Misbranded because falsely represented on cartons and in circulars as efficacious for treating goiter, constipation, scurvy, thyroid disturbances, stomach troubles and some other things.—[D D N J F D C 374 March 1942]

Wonder Dandruff Cure—Wonder Dandruff Cure Company, Cedar Rapids, Iowa, Aug. 3, 1940. Composition: an artificially colored perfumed watery solution containing arsenic, alcohol and glycerin. Misbranded because falsely claimed on the label to eradicate dandruff, restore lifeless hair to a healthy natural condition, prevent it from coming out and stop irritation and itching of the scalp. Further misbranded because label did not bear the common name of each active ingredient or an accurate statement of the amounts of alcohol and arsenic present.—[D D N J F D C 363 March 1942]

World Famous New Life Laxative Tonic—Harry B. Kohn trading as New Life Medicine Company, Atlanta, Ga., Between Oct. 2 and Dec. 7, 1939. Composition: epsom salt, free sulfur, senna, anise, cayenne and unidentified material. Misbranded because falsely represented to improve health, cleanse the system, act as a tonic and be an effective treatment for a long list of disorders. Defendant found guilty and placed on probation for one year.—[D D N J F D C 375 March 1942]

World's Tonic Compound with Alkalines—World's Medicine Company, Columbus, Ohio, July 6, 1940. Composition: essentially plant drugs including sassafras, licorice and laxatives such as aloes and emulsion bearing drugs together with 12 per cent of alcohol and small amounts of iron, strychnine and alkaline substances. Misbranded because though essentially a laxative it was falsely represented as a tonic and a source of alkalis. Further misbranded because nuxvomica content was incorrectly declared.—[D D N J F D C 361 March 1942]

Correspondence

PREVENTION OF RENAL COMPLICATIONS IN USE OF SULFONAMIDES

To the Editor —Drs Keitzer and Campbell report in THE JOURNAL of June 27 having seen 11 patients with renal symptoms or anuria due to sulfadiazine alone, and as many patients with renal complications due to the other sulfonamides. Since April 1940 when the case of hematuria from sulfathiazole therapy occurred which I reported in THE JOURNAL of Aug. 3, 1940, I have treated 67 cases with sulfathiazole and 75 cases with sulfadiazine without experiencing any such complications. At that time I adopted a simple procedure which is as applicable to treating 'a soldier in the jungles of Malaya or the deserts of northern Africa' as here at home. The only equipment required is a transparent container. In this the last urine passed is exhibited at all times in a prominent place near the patient. Every time the patient voids the old sample is discarded and the new one substituted. The nurse sees it, the intern sees it and I see it (or if I do not I ask the reason why). If the urine contains many sulfonamide crystals when it is first passed it looks muddy. The crystals soon settle into a yellowish brown layer at the bottom of the container. Orders are given that if the freshly passed urine appears muddy the fluid intake is to be increased or the sulfonamide dose decreased or both. If the urine appears bloody the sulfonamide medication is stopped until further orders from the physician in charge. A fluid intake of at least 2,500 cc and a urine output of at least 1,500 cc are of course always insisted on. Since the renal complications of sulfonamide therapy are the result of the precipitation of crystals in the urinary tract and since such precipitation is discernible in the voided specimen muddy or bloody urines are respectively interpreted as caution or stop signals, which if promptly heeded, will prevent accidents.

JOHN H. ARNETT, M.D., Philadelphia

DENTAL CARIES AND DIET

To the Editor —Evidence based on clinical and experimental research indicates that dental caries may be caused by an insufficient intake of certain minerals and vitamins or to the ingestion of excessive amounts of sweets and other carbohydrates.

The sugars and flours from which these carbohydrate foods are made are those which through processing have been deprived of many of the vitamins, amino acids and minerals they naturally contained. As a result such diets are more or less deficient in elements essential for their normal cellular metabolism.

Timothy Leary and others have presented both clinical and experimental evidence to indicate that "atherosclerosis the important form of arteriosclerosis, is a specific disease due to excess cholesterol" (THE JOURNAL, July 25, 1942, p. 1041) or to excessive intake of fats.

In man, much of the fat in the diet comes from butter, cream and egg yolk, some from vegetable or other animal fats and oils. Certain minerals, vitamins and essential amino and fatty acids are required for the normal cellular metabolism of the lipoids. They are present in whole milk, whole eggs and some of the natural animal and vegetable fats in adequate amounts. They are not present in adequate amounts in butter, cream, egg yolk, some of the other animal and certain of the commonly used vegetable fats and oils.

There is also evidence that dental caries does not develop when a diet high in carbohydrates but containing adequate minerals, amino acids and vitamins is consumed. Then there is immunity to caries. Similarly the experimental production of atherosclerosis in laboratory animals can be inhibited when the high fat or high cholesterol diet contains adequate amounts

of the minerals, vitamins, hormones, and essential amino and fatty acids required for their normal cellular metabolism.

Therefore would it not be more accurate to state that the results of clinical and experimental research indicate that dental caries and atherosclerosis may be due to relative dietary deficiencies than it is to ascribe such lesions to an excess of carbohydrates, cholesterol or fats in the diet?

N. S. DAVIS III, M.D., Chicago

FAILURE OF SULFONAMIDE DRUGS TO INTERFERE WITH ANTIBODY RESPONSE

To the Editor —A recent editorial (THE JOURNAL May 23, p. 346) comments on the failure of sulfonamide drugs to interfere with spontaneous antibody responses to pneumococcal infections as illustrated by Curnen and MacLeod's (*J. Exper. Med.* 75:77 [Jan.] 1942) experimental observations with rabbits. In the course of that editorial papers of Kneeland and Mulliken (*J. Clin. Investigation* 19:307 [March], 735 [Sept.] 1940) and of Bukantz and de Gara (*J. Immunol.* 39:195 [Sept.] 1940) are quoted to illustrate unfavorable results of antibody study in cases of human pneumococcal pneumonia treated with sulfonamide drugs. The figures attributed to Bukantz and de Gara are somewhat misleading in this regard since the figures had been incorporated in the paper quoted only in a discussion of a method of testing for pneumococcus precipitins in human serum. When the precipitin reaction is the sole immunologic test employed (as by Kneeland and Mulliken) antibody responses are of low frequency because the precipitin reaction is considerably less sensitive than is the agglutination reaction in detecting the low titers of antibody which develop in the convalescent case of pneumococcal pneumonia.

This subject is discussed more fully in a later paper of Bullock, de Gara and Bukantz (*Arch. Int. Med.* 69:1) in which the complete figures on human antibody responses are given. During that investigation 65 patients treated with sulapyridine alone were studied. Of these, antibodies were detected in 45 or 69.2 per cent (table 1, p. 3). The serum of 22 of the antibody producers gave a precipitin reaction as well as an agglutination reaction while the serum of the remaining 23 were positive by the agglutination reaction alone. Thus if the precipitin reaction alone had been utilized to demonstrate antibody only 22 of 65 or 33.8 per cent would have been detected, instead of the 69.2 per cent detected when the agglutination test was employed. Our clinical conclusions were therefore in agreement with those of Finland, Spring and Howell (*J. Clin. Investigation* 19:179 [Jan.] 1940) and with the experimental observations of Curnen and MacLeod: i.e., antibodies develop in sulapyridine treated subjects with about the same frequency as in untreated subjects.

SAMUEL C. BUKANTZ, Washington, D. C.

First Lieutenant, M. C., Army Medical School

BIBLICAL QUOTATION

To the Editor —Will you kindly call attention to an error in Biblical quotation on page 922 of THE JOURNAL July 18 made by Dr. Post. 'The years draw nigh when thou shalt say 'I have no pleasure in them' is not to be found in the Lamentations of Jeremiah but is the first sentence in the twelfth chapter of the book of Ecclesiastes attributed to King Solomon. It is an unintentional error quoted probably from memory. The corrected version reads:

Remember now thy Creator in the days of thy youth
While the evil days come not
Nor the years draw nigh when thou shalt say
I have no pleasure in them

AARON BRAY, M.D., Philadelphia

THIAMINE IN THE AMERICAN DIET

To the Editor—After reading the editorial entitled "Thiamine in the American Diet" in the July 25 issue of THE JOURNAL, I have to ask the following question: Do the figures mentioned represent the actual amount of vitamins in the daily diet as found after cooking, preserving, storing and transporting or do they represent the ideal amount of nutrients without regard to destructive processes? In other words, do these figures give one the true amount of vitamins one takes when one sits down at the table for dinner?

EDMUND F KOHL, M.D., New York

COMMENT—In the study of thiamine in the average American dietary (Lane, R L Johnson, Elisabeth, and Williams, R R *J Nutrition* 23 613 [June] 1942) the effort was made to prepare the food, prior to the determination of the thiamine, in a way which represents ordinary kitchen practice. Foods like meats and certain vegetables were cooked before assaying for thiamine, whereas the fruits and the salad vegetables were assayed in the raw state. In other words, the data indicate the amount of thiamine actually eaten in this average American dietary.—Ed

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore 12 281 338 (June) 1942

Use of Heparinized Blood in Studies with Congo Red and Bromsulphalein. I E Gerber and Marja Gryczynski. Jersey City, N J—p 312.
Wassermann Reaction in Infectious Mononucleosis with Special Reference to Kolmer Test. J A Kolmer, I W Ginsburg and Elsie R Lynch. Philadelphia—p 316.
Primary Liver Cell Carcinoma in Infancy. Report of Two Cases. One Showing Calcification. W J Tomlinson. Santa Barbara, Calif. and F Wolff. Montgomery, W Va—p 321.
Nonspecific Fixation of Complement (Guinea Pig Serum) by Three Lots of Kolmer Antigen. B E Diamond with technical assistance of Bernice M Iverson. Vermillion, S D—p 328.

Bacteriophage Treatment of Staphylococcemia.—From the data on 500 cases of staphylococcemia MacNeal and his associates conclude that staphylococcal infection occurs at all seasons with little variation. There is an apparent rise in the recovery rate during the fall months. Staphylococcemia occurs at all ages in both sexes. The prognosis of the disease is distinctly less favorable after 40. The staphylococci isolated from the blood stream are generally susceptible to the (in vitro) action of bacteriophages now available. Early recognition of signs and symptoms, skill and willingness to carry through the rather exacting program of bacteriophage therapy and the use of accessory therapeutic measures appear of greatest significance for a high rate of recovery. Only 5 (17 per cent) of 30 patients who did not receive bacteriophage therapy survived as compared to 18 of 25 who received bacteriophage during the metastatic stage of the disease. Of the remaining 445 patients, 137 died before the end of the third day after bacteriophage treatment was started. These are arbitrarily considered as moribund patients. Of the 308 who received bacteriophage earlier 142 (46 per cent) survived. Of the total 470 patients who received bacteriophage therapy 160 (34 per cent) survived. Bacteriophage in conjunction with other agents particularly sulfathiazole and fractional transfusions offers a more favorable outlook in the severe forms of staphylococcal infection.

American Journal of Diseases of Children, Chicago 63 1019-1232 (June) 1942

- Period of Resistance in Early Childhood. Its Significance for Development of the Problem Child. E Benjamin. Baltimore—p 1019.

Children's Feet. Normal and Presenting Common Abnormalities. F A Chandler. Chicago—p 1136.

Childhood Appendicitis.—From a statistical investigation of 918 children up to 12 years of age with nonperforating and perforating appendicitis, Jacobson finds that a definite correlation of diagnostic and prognostic importance exists between

the degree of leukocytosis (with its associated proportional rise of polymorphonuclear leukocytes and temperature) and the incidence of peritonitis. There was no relation between the leukocytosis and the incidence of appendiceal abscess. The leukocyte-pulse rate index aided in determining the degree of resistance of patients with peritonitis. Chronic appendicitis as a definite clinical entity is comparatively unusual in childhood (39 cases among the series) and occurs most frequently after repeated subclinical attacks. Sulfanilamide orally and parenterally to patients with peritonitis apparently definitely reduces the mortality (89 per cent during 1934 and 1935, 4 per cent during 1936, 1937, 1938 and 1939 to 0 in 1940) and morbidity of perforating appendicitis.

Sulfapyridine as Hemostatic Agent.—Cunningham found that the application of powdered sulfapyridine and sulfamethylthiazole to experimental wounds in the horse, guinea pig and rabbit uniformly controlled vascular oozing. The results of the experiments confirmed his observations in cases of delayed and secondary tonsillar hemorrhage in which the drugs also successfully controlled persistent bleeding. A 40 per cent solution of sodium sulfapyridine was equally efficacious experimentally. The exact mechanism at work is open to conjecture. Sulfanil-

amide and sulfathiazole powders and talc had little hemostatic value. The beneficial drugs, finely powdered, were easy to apply if they were kept dry and were insufflated by a powder blower directly on the surface of the wound. The tonsillar hemorrhage in the patients treated was not amenable to routine management. The routine postoperative use of sulfapyridine in the tonsillar fossa might tend to prevent secondary hemorrhage.

Nutritional Deficiencies in Otolaryngology—Roberts suggests that the following symptom complex be considered a syndrome: postnasal discharge without sinus infection, nasal stuffiness or seeming obstruction, sinus pain without sinus infection and fatigue without organic changes. These and many other symptoms, such as auditory neuritis without discoverable etiology and nervous psychoneurotic symptoms without positive signs, are frequently present. Postnasal discharge is the most common; it causes much clearing of the throat, cough, a sensation of fullness and sometimes actual choking sensations. Nasal fullness or obstruction is frequently alternating from side to side and is worse when lying down and in the early morning. The chief dietary faults are excessive use of sugar and white flour. To investigate the nutrition properly a careful history of the diet must be taken. Four well known factors that deplete the body of vitamin B complex are excessive alcohol, excessive smoking, excessive intake of carbohydrates and the pernicious habit of cathartics. The author has given over seven hundred intravenous doses of riboflavin 2 mg., pyridoxine hydrochloride 1 mg., pantothenic acid (as the calcium salt) 1 mg. and nicotinamide 100 mg. He has added to the foregoing 50 mg. of thiamine hydrochloride. He is convinced that the results obtained with this medication are more satisfactory than when only nicotinamide was used intravenously or orally. Eight to ten intravenous doses over three to four weeks are usually needed to replenish the depleted vitamins. Therefore oral administration may be ample for maintenance.

Mixtures of Soluble and Protamine Zinc Insulin—The need in severe diabetes of an insulin with an action between that of soluble and that of protamine insulin prompted Colwell and his associates to investigate the effects of mixtures of the two insulins on 3 patients (respectively 66, 62 and 56 years of age) with mild diabetes mellitus. None had used insulin routinely and none had shown any previous rapid change in severity of their diabetes. All were fed every four hours day and night throughout the experimental period of two or three months. All injections were made subcutaneously and all traces of insulin effect from a previous injection were allowed to disappear before a subsequent injection was made, a process usually requiring three to four days. Regular insulin in sufficient quantity added to protamine zinc insulin increased the promptness and intensity of the sugar reducing response. The response depended on the proportion of regular insulin added. The response was uniform and therefore predictable within the limits of error involved in any form of insulin therapy. Practical application of the mixtures was restricted to observation of 12 selected patients with severe diabetes of the juvenile type.

The mixtures used contained 60 to 75 per cent of ordinary insulin and 40 to 25 per cent of protamine zinc insulin in single daily doses. With supplementary injections of soluble insulin the severe diabetes of 8 of 9 patients who were previously imperfectly controlled on protamine zinc insulin was under decidedly better control with a single daily dose of a 2 to 1 or 3 to 1 mixture than with a single daily dose of protamine zinc insulin supplemented by one or two small daily doses of soluble insulin. One patient reverted to separate injections after trying a 3 to 1 mixture for three weeks, an infection of the respiratory tract during the trial period probably vitiated the results. The diabetes of the other 3 patients was satisfactorily controlled with protamine zinc insulin alone; control was fully as good with a 2 or 3 to 1 mixture. The chief difficulty was a tendency to hypoglycemia in the late afternoon. For some patients reducing the total dose or increasing the noon meal and a midafternoon feeding were sufficient to prevent hypoglycemic symptoms without increases in glycosuria at other times. For others, mixtures containing less soluble insulin may be preferable. In practically all instances there was a substantial reduction in dose necessary when mixtures were used.

Epidemiology of Western Equine Encephalitis—In reporting the epidemic of poliomyelitis and encephalitis in Manitoba in 1941, Donovan and Bowman state that encephalomyelitis in horses was on the wane when the human cases started. Only 9 persons who contracted the disease gave a history of having had contact with sick horses. Thus spread by such contact may probably be ruled out except for the few

cases in which direct blood infection may have taken place through an abrasion in the skin. Patient contact may be entirely ruled out, barring accidental inoculation. However, in spite of this there were many cases of mild illness which may have represented subclinical infection. It is not known how the virus enters or leaves the body, but it can be isolated from the brain, cerebrospinal fluid and blood during certain periods of the disease. Toward the end of the epidemic a physician made a complete survey of 120 cases (50 urban and 70 rural). The patients' homes and families were visited, histories obtained and patients examined. From the mass of information obtained and studied the following facts stand out: 1. Almost 100 per cent were exposed to mosquitoes. 2. Many cases were first diagnosed as sun and heat stroke. 3. Owing to the war many people were short of help and worked overtime, that is they were overworked. Many older people who had retired started to help and worked harder than they had for years. 4. No significant information as to occupation was elicited, except that outdoor workers predominated. Many birds and animals may harbor the virus. The reservoir may be some insect vector. More work must be done on birds, animals and biting insects common to the various areas where encephalitis appeared. There were 78 deaths, giving a case fatality rate of 15.3 per cent.

Encephalitis (Western Equine)—The widespread epidemic of western equine encephalitis in Manitoba offered an excellent opportunity for Adamson and Dubo to study the clinical signs and symptoms. They examined 266 patients with a tentative diagnosis of encephalitis who were admitted to hospitals in Winnipeg and St. Boniface. The diagnosis was confirmed in 212, who constituted 50 per cent of all cases notified in the province. Subjectively the dominant features were head ache in 96.3 per cent, disturbance of sleep in 71.3 per cent and spinal pain in 62.3 per cent. The characteristic constitutional effects were not unlike those of deep alcoholic intoxication: drowsiness, indifference, thick speech and staggering gait. The neurologic signs were like those in disseminated sclerosis: nystagmus, intention tremor, absent abdominal reflexes, an up-going toe and jerky speech. The great difference from case to case was not in the variation in the symptoms present but in the intensity of all signs and symptoms. An extremely mild case of encephalitis may produce a picture almost identical with that of poliomyelitis, and unless there is tremor, nystagmus or monocytic spinal fluid or a flaccid paralysis supervenes differentiation cannot be made without a serologic test.

Dietary Deficiency and Leukoplakia—Abels and his associates examined 17 adults with papillary atrophy of the tongue, 29 with lingual buccal, mucosal, gingival and cheilar leukoplakia and 21 with both lingual and cheilar leukoplakia to determine their relative etiologic importance to tobacco, syphilis and dietary deficiencies. For controls the following subjects were examined: 25 normal adults, 20 women with mammary cancer, 12 males and 13 females with gastric cancer and 10 men and 5 women with leukemia. These subjects were

studied only to ascertain the incidence of syphilis, excessive smoking and dietary deficiency among them. The figures for syphilis, excessive use of tobacco, history of dietary deficiency, dietary deficiency or gastric achlorhydria and dietary deficiency, gastric achlorhydria or hepatic insufficiency for the 17, 29 and 21 patients and 25 normal subjects were respectively 0, 18, 59, 76 and 82 per cent, 11, 55, 55, 61 and 65, 4, 5, 46, 61, 81 and 81, and 4, 8, 12, 0 and 16. The incidence of dietary deficiency and excessive use of tobacco were high among the patients with papillary atrophy of the tongue with oral leukoplakia and with combinations of these lesions. The dietary deficiency of many patients was confirmed by the finding of a low plasma level of vitamin A and low urinary excretion of riboflavin. The pathologic changes associated with papillary atrophy of the tongue and oral leukoplakia presented by the patients studied were hepatic dysfunction, anatomic and functional abnormalities of the gastrointestinal tract, anemia, ungual deformities, cheilosis and perleche. Hepatic dysfunction and gastrointestinal abnormalities might have contributed to the dietary deficiency. Large quantities of brewers' yeast given to patients with papillary lingual atrophy or oral leukoplakia occasionally resulted in a complete or partial remission of the lesions and oral symptoms. This suggests a relationship between such lesions and an inadequate intake of certain dietary factors present in yeast.

Serum Acid Phosphatase in Carcinoma of Prostate—Herger and Sauer determined the serum acid and alkaline phosphatase of 430 patients. 283 suffered from a variety of diseases other than prostatic cancer, and 147 were diagnosed as having carcinoma of the prostate. The value for serum acid phosphatase activity in the 283 control cases was invariably below 6 King Armstrong units, but 77 of the 147 had a serum acid phosphatase level below 4 units once or on repeated determinations. Only 1 patient was shown to have a serum acid phosphatase activity of more than 6 units. Twenty-two patients had a serum acid phosphatase level of from 4 to 6 units. These values represent borderline figures which are diagnostic for metastatic osseous lesions from carcinoma of the prostate only if further elevation takes place. With one exception such an elevation was not encountered in the controls or in patients not suspected of having osseous metastasis from carcinoma of the prostate. Definite metastasis to the bones demonstrable roentgenologically, was present in 39 of the 147 patients. In 4 the serum acid phosphatase level was below 4 King Armstrong units, in 2 between 4 to 6 and in 33 it was above 6 units. The data presented are limited to figures obtained on patients prior to castration or diethylstilbestrol medication. A relationship between the degree of the elevation of serum acid phosphatase and the extent of metastatic osseous involvement could not be established.

Testosterone Propionate and Nocturia—Greenblatt implanted pellets of testosterone propionate subcutaneously for the treatment of various gynecic disorders in 63 women from 25 to 58 years of age. Evaluation of complaints yielded the information that 28 were regularly disturbed two to ten times by urgency after retiring. Frequently diurnal frequency and dysuria were associated with the nocturia. Of the 28, 3 were menopausal cases and 19 had uterine fibromyomas with or without menstrual irregularities. In each of the 28 the nocturnal frequency was wholly or in greater part alleviated after pellet implantation. In several the symptoms partially or wholly recurred after the pellets were completely absorbed. The amelioration of frequency following steroid therapy may be a direct sequence to the action of the substance on renal function, tone of the bladder, pituitary activity, water balance, electrolyte metabolism or some other mechanism at present not understood. From 25 to 400 mg of sterile crystalline testosterone propionate in pellets may be implanted subcutaneously without fear of arrhythmetic phenomena.

Pyridoxine for Adolescent Acne—Jolliffe and his co-workers used pyridoxine for the treatment of 37 of 72 patients with persistent adolescent acne, the remaining 35 patients were used as controls. The condition of 9 of the 37 was cleared, of 19 improved, of 6 unchanged, and 3 dropped

from treatment. The respective figures for the controls were 0, 7, 19 and 9. The initial dose of pyridoxine was 25 mg two times a day. This was increased as necessary to 250 mg (50 mg five times a day) in several subjects before the lesions definitely improved or actually cleared. Irrespective of the degree of improvement of the acne there was a decrease in the oiliness of the skin. Generally it took seven to ten days of continued administration of the effective dose of vitamin B₆ to obtain definite improvement. Improvement remained stationary without treatment in only 4 subjects. In the others relapses occurred when treatment was withdrawn. It is doubtful whether in the 4 the apparent improvement was due to pyridoxine. It is suggested that the physiologic function of pyridoxine is connected with utilization of the unsaturated fatty acids, pyridoxine probably functions through its corrective action on a deranged fatty acid or lipid metabolism. This suggestion would not invalidate the concept of a direct physiologic action of pyridoxine on the activity of the sebaceous apparatus of the skin and the reduction in the oiliness of the skin.

Treatment of Arthritis by Electropyrrexia—Osborne and his co-workers used electropyrrexia in the treatment of 27 patients with rheumatoid arthritis whose temperature was elevated by using a fever cabinet in combination with an induction therm. The intake of fluid (a 0.4 per cent solution of sodium chloride) was limited to 250 cc for each fifteen minutes of pyrexia unless more could be given without causing distress. Nausea or vomiting was seldom encountered. A rectal temperature of 104 F was maintained for four hours. In only 6 of the patients were the results sufficiently striking for one year or longer to be classified as definitely improved, 6 were moderately improved, 9 slightly improved and 6 experienced no benefit. In not 1 could the designation "cured" be used.

Hemophilus Influenzae Infections in Infancy and Childhood—The three severe infections in which bacteremia is a constant feature due to strains of encapsulated Hemophilus influenzae are meningitis, obstructive infection of the respiratory tract and pneumonia accompanied by empyema in infants less than 1 year old. According to Alexander and her colleagues susceptibility to bacteremia is due to a lack of immunity of the infant or child, in contrast to the adult, who is relatively resistant to this organism. The difference in this bactericidal property of the blood is believed to be due to antibody. If this assumption is correct, the production of antibody should be possible in patients who recover under sulfonamide without complementary serum therapy. The authors' experience includes evidence of complete recovery of 1 patient with a relatively mild type B H influenzae meningitis with sulfanilamide alone for five days. The spinal fluid contained 900 cells per cubic millimeter, but no organisms were seen in stained smears, and the sugar and chloride were normal. After three days of incubation the original spinal fluid grew type B H influenzae. By this time the child's general condition, temperature and spinal fluid showed striking improvement, her serum agglutinated a suspension of encapsulated H influenzae. The child recovered without serum. Such evidence along with polysaccharide cutaneous tests for detecting antibody may prove of value in separating the patients who require added antibody for recovery from those who have formed sufficient immune substance as a result of a mild infection efficiently suppressed by early chemotherapy. Factors other than antibody, which is so closely correlated with age, play a part. With chemotherapy

alone, meningitis of average severity may be held in a static phase for a long period, provided treatment is not interrupted and adequate levels of the drug are maintained. If the infection is mild from the beginning and sulfonamides are started early, the natural antibody formed by the host in response to the infection is sufficient for complete recovery. However, as many institutions and most private practitioners lack facilities for demonstrating free antibody, it is best that all patients suffering from meningitis and obstructive infections of the respiratory tract and infants less than 1 year of age with empyema and bacteremia be given type specific rabbit antibody in addition to sulfonamide therapy. Thirty seven of the authors' 50 patients with meningitis recovered as did 14 of 20 with infections causing respiratory obstruction.

Hemophilus Influenzae (Type B) Meningitis in Children—Neter reports his observations in 62 cases of Hemophilus influenzae meningitis in children. A study of the incidence of bacteremia revealed that H influenzae was present in the blood of 11 out of 17 children. In 4 the location of focus was the throat and bronchi. Intraventriculobronchitis necessitated tracheotomy in 2 patients with H influenzae meningitis. In 3 patients H influenzae was present in the middle ear. In 1 H influenzae septicemia with purulent arthritis preceded the meningitis by three weeks. The results of chemotherapy and serotherapy were as follows: 1. Three patients received sulfonamide compounds exclusively. 1 treated with sulfathiazole recovered completely. 2. Two of 12 patients who received anti H influenzae horse serum in conjunction with chemotherapy recovered. 3. Of 7 patients who received anti H influenzae rabbit serum and chemotherapy. 4 recovered completely, 1 of these had two attacks (relapse?) of H influenzae meningitis within six weeks. Following treatment with rabbit serum antibodies were demonstrated in the blood of 2 patients at a time when viable organisms and specific soluble substance of H influenzae were present in the spinal fluid. It is suggested that these patients be kept desensitized to the therapeutic serum for several weeks until, as far as it is possible to judge, permanent recovery has been established.

Local Use of Sulfonamides—Klepser states that more important than the sulfonamide drug to be used is the proper surgical preparation of the wound for the reception of the drug. Sulfonamide therapy is not a substitute for surgical judgment and meticulous care. Deep, pocketed wounds and inaccessible walled off abscesses or draining fistulas are not benefited by the drug unless the wound is first converted into an open access-

sible area by proper surgical drainage. As there may be limited diffusion into surrounding tissues following local application of the powdered drug, sulfanilamide, which is the most diffusible and readily absorbed, is frequently preferred to the other sulfonamide derivatives. The rapidity of wound healing in their presence is still an unsettled subject. Retarded healing has been reported by some workers, and others have disclaimed this. Biopsies of the wound edges of seventy infected wounds, most of which were undermined infected decubitus ulcers, were taken at frequent intervals during treatment. In no instance was there gross or microscopic evidence that sulfanilamide interfered with the normal physiology of healing. There was no evidence that the drug destroyed fibroblasts or epithelium. However, the powder is slowly absorbed and in fairly clean incised wounds it may prevent early contact of the contiguous edges of the wound, thus slowing healing. But such wounds when healed appear fully as strong as when the drug is not used and there is just as little scar tissue. Its topical application in any contaminated or infected wound is certainly advantageous, but its routine use in clean operative wounds in which normal healing is expected is discouraged. Microscopic sections of the granulation beds of infected ulcerations and infected burns after prolonged use of a powdered sulfonamide derivative revealed that healing gradually became slowed, and granulation tissue appeared pale, dried out, inert and dull. Although infection was controlled, the wounds remained inert and the healing time in them was definitely prolonged. If sulfonamide therapy was stopped healing usually was resumed, but occasionally reinfection occurred. This problem was solved by substituting a greaseless ointment base for the dry powder and by using only 10 per cent of the sulfonamide drug, which proved adequate to prevent infection. To encourage granulation 2 per cent of allantoin was added to the base. Toxic manifestations from local use were infrequent.

Unpooled Liquid Human Plasma—The reactions which followed fifteen hundred consecutive intravenous infusions of liquid unpooled human plasma are discussed by Weinstein. The infusions were carried out and observed by him throughout the entire period of administration. The plasma was given in variable amounts (the average amount was 500 cc) by a filter drip method with varying rates of flow. Fifteen reactions of mild to severe chills with or without a rise in temperature and urticaria in 1 patient occurred. It was not always possible to elicit the cause. Some reactions may be avoided by using fasting donors, using a completely closed and simple method for preparing and storing plasma, repeated bacteriologic studies to insure sterility and by utilizing an accepted, thorough, well defined and well supervised procedure for preparing and caring for all equipment and solutions used in conjunction with the preparation, storage and administration of plasma.

Hypertrophic Gastritis—Nearly 25 per cent of 800 patients who had a gastroscopy performed at the University Hospital showed typical morphologic characteristics of hypertrophic gastritis. Pollard and Cooper selected 50 of these patients, entirely free of any other evidence of organic disease to determine whether or not they presented any consistent clinical picture as a result of their disease. The features which were commonly present and should serve as a diagnostic aid were a burning sensation or discomfort in the epigastrium before

immediately after or in about two hours after eating. The discomfort was at times relieved by food or sodium bicarbonate. Free acid in the gastric contents in normal or increased amounts was common. The roentgenogram revealed no significant change. The disease was more prevalent in men than in women. It was not confined to any particular age group. With such a variable picture the diagnosis appears to depend on direct gastroscopic observation of the gastric mucous membrane. The diagnosis is important as hypertrophic gastritis is a definite organic disease. Not infrequently it explains the symptoms in patients with gastric complaints but negative roentgenograms. Also hypertrophic gastritis may be the cause of a small or massive gastric hemorrhage, it may be the explanation of significant occult blood in the stool. The gastric analysis showed a maximal free acidity of more than 50 degrees in 58 per cent of the patients, in 18 of these it reached more than 80 degrees. None of the patients showed an achilohydria in all gastric specimens. As no characteristic clinical syndrome is typical of hypertrophic gastritis the diagnosis must be made by exclusion and by gastroscopy.

Pneumonia Treated with Sulfathiazole—Rosenthal and his associates report the results of 132 indigent patients with pneumonia treated in their homes during the winter of 1940-1941 by the Domestic Medical Service of the Boston Dispensary. The conditions were adverse but, as the total mortality (5 patients, or 3.8 per cent) indicates, pneumonia can be treated successfully in the home by the early use of the sulfonamides. Pneumococci in the sputum were obtained from 70 patients, and 6 had positive blood cultures. The mortality rate for those with pneumococci in the sputum was 6 per cent. Toxic manifestations due to the drug were few, and there were no instances of hemolytic anemia or granulocytopenia. This work represents a financial saving to the community of several thousand dollars that would have been incurred had the patients been treated in hospitals. Supportive treatment consisted mainly

of a high calory diet, sedation for chest pain, general nursing care and the tender ministrations of the patient's own family. No oxygen, digitalis or artificial stimulants were used.

Behavior Disorders in Children—At the Boston Psychopathic Hospital, Secunda and Finley obtained electroencephalographic tracings of 143 children presenting behavior disorders. A poorly integrated personality was brought out by the number who had a history of neurotic traits (enuresis, nail biting, walking and talking in their sleep), 90 had one or more neurotic traits, 32 had none, and no information was had on 21. Of the 143 children 26 had normal, 23 borderline and 51 per cent abnormal electroencephalograms, whereas of 76 control children 68 had normal, 17 borderline and 15 per cent abnormal tracings. As a group, the electroencephalograms of the children with behavior disorders were more vulnerable to hyperventilation than those of the controls. On the whole there was a progressive increase in normal records and a diminution in abnormal records with increase in age. The intelligence of 24, or 16 per cent, of the children with behavior disorders was inferior, and of these 15 (62 per cent) had abnormal tracings. Of the 119 who had normal intelligence 59 (50 per cent) had abnormal tracings.

Vitamin B₁ and Endurance—Karpovich and Millman attempted to determine whether endurance could be improved by a daily dose of 5 mg of thiamine hydrochloride. Sixty-nine subjects of college age divided into three groups were tested for the time they were able to hold their arms horizontally. The first group were simply told to hold their arms outstretched as long as possible, and their holding time ranged from six to one hundred and eight minutes. The second group were given a "pep talk," and their range of endurance varied from eight to one hundred and thirty-five minutes. The third group, tested two days after the first two groups and naturally who had been talking about the "remarkable" feat of holding the arms outstretched for one hundred and thirty-five minutes, were given an especially emphatic "pep talk," and their range varied from nine to two hundred and sixty minutes. Forty-one of the 50 men whose arm holding times were less than thirty minutes were given either 5 mg of thiamine hydrochloride a day or a placebo (5 mg of lactose). A week later these 50 men were given a second test. The range of those given the placebo varied from five to seventy-seven minutes and that of those given the vitamin varied from seven to seventy-nine minutes. In the latter, 8 of 16 improved and, in the former, 12 of 25 improved. The study proved that the arm holding test cannot be used as a test for the effect of the vitamin in apparently normal people or for vitamin B₁ at all because the test is definitely affected by psychologic factors. The "pep talk" and the competitive elements. Also the breath holding test before and after a diet containing 5 mg of thiamine hydrochloride a day for a week or 5 mg of lactose was influenced by psychologic factors and not by the vitamin B₁. Therefore neither test appears to be a criterion for determining vitamin B₁ deficiency in apparently normal college students.

Pili Torti Hereditaria—The occurrence of hereditary pili torti in 2 sisters is reported by Appel and Messina. Hypoplasia of the enamel of the teeth in the older girl was another characteristic feature that points to ectodermal dysplasia as a probable underlying cause. The authors are in accord with Ronchese that a twisting of the hair on its own axis is the pro-

nounced feature, this should determine the name of the condition—"pili torti"—and "hereditaria" added because of the obvious hereditary character. The cause of the condition is most likely a developmental anomaly. As the patients become older their hair tends to become less abnormal in appearance. The application of hydrous wool fat is the only effective treatment.

Vascular Disorders of Extremities J. Homans, Boston—p. 951

Mitral Stenosis—Patients with mitral stenosis, Burgess and Ellis state, may often complain of pain due to cardiac neurosis, active rheumatic carditis, angina pectoris or so called hypercyanotic angina. In none of these is the pain directly produced by the stenosed mitral valve. These patients are also prone to repeated pulmonary infarction. The pain may be pleural or substernal, especially with massive pulmonary infarctions or emboli. The last three types of pain are severe, squeezing or grinding, located in the precordium or beneath the sternum, radiating to the left shoulder and arm; they bear no clear relation to exertion, emotion or stress and they occur in paroxysms that may last for hours or days. Usually dyspnea, orthopnea and a severe degree of cyanosis are present during attacks, and sometimes circulatory collapse. Peripheral venous congestion may or may not be present. The fever, leukocytosis or electrocardiographic pattern of an acute myocardial infarction are not present, and the changes in blood pressure are irregular and in no way characteristic. Oxygen relieves the pain much more effectively than vasodilator drugs. Consequently the pain is probably due to anoxia in a hypertrophic and fatigued myocardium. Postmortem examination shows a high degree of mitral stenosis, with secondary myocardial hypertrophy and pulmonary vascular changes. This symptom complex, which is by no means new, is seen occasionally in most large clinics. It is confusing and often leads to a mistaken diagnosis of myocardial infarction. The subject has received relatively little attention and is not mentioned in most standard textbooks. Mild grades of the syndrome may occur in patients with well defined mitral stenosis, and therefore the syndrome may not be as uncommon as observers believe.

Treatment of Vaginitis with New Synthetic Phenol Derivative C Schaefer Staten Island N Y—p 243

Spontaneous Pneumothorax—Ornstein and Lercher do not believe that spontaneous pneumothorax in apparently healthy individuals is as rare as Kjaergaard suggested (51 cases from the hospitals in Denmark in more than twenty years) and are presenting their 58 cases encountered in the last twenty years. The material includes only ambulatory patients who came to the office for diagnosis and treatment. The pathogenesis of spontaneous pneumothorax is based on the development of emphysematous blebs in the pleura produced by rupture of the elastic fibers of the subpleural alveoli into the alveolar layer of the pleura. The pleura is lifted and separated from the underlying layer of alveoli. The blebs are formed because the air forced from the bases of the lungs into the apexes of the upper lobes distends and ultimately ruptures the elastic fibers of the alveoli. Air is forced into the upper lobes more frequently in the muscular robust male adult, who is more apt to overdistend his upper lobes by severe exertion when the expiratory and abdominal muscles are contracted, and the glottis is closed. The blebs may form in lungs free of any disease or in peripheral subpleural scar tissue resulting from previous nontuberculous or tuberculous infection. A further step in the pathogenesis is that spontaneous pneumothorax occurs in emphysematous blebs with a check valve mechanism. The bleb, consequently enlarges and thins out to such an extent that it cannot further resist the increase in pressure and bursts. The extent of the pneumothorax depends on the size of the emphysematous bleb and the elasticity of the adjacent pulmonary tissue. Only 2 of the authors' patients were female. The average age of the group was 28, the youngest being 15 and the oldest 56. Only 10 of 45 gave a history of exertion. Sudden sharp thoracic pain and extreme dyspnea were the principal symptoms. Roentgenograms of the lungs should be taken in deep expiration to detect small pneumothoraces that may be overlooked on deep inspiration. Small pleural effusions occurred in 22. In the 41 who had only one attack the right lung was involved twenty five times and the left sixteen times. Seventeen had recurrences and both lungs were involved in 6 of the 17 who had recurrences. In 3 of the 58, pulmonary tuberculosis developed about two years after the lungs were reexpanded.

Fever in Intestinal Involvement—Tchertkoff and Green present the data from 221 cases to demonstrate that it is not the duration, the extent of the pathologic changes or even the mere presence of tubercle bacilli, but rather the activity and progression of the disease that are the determining factors in the development of intestinal tuberculosis in chronic pulmonary tuberculosis. They chose the temperature curve as a single index of this activity. Only a persistently elevated temperature can be considered as evidence of activity and progression. From the data the conclusion appears warranted that intestinal disease can be diagnosed in a case of pulmonary tuberculosis uncomplicated by empyema when a febrile course of more than two months is exhibited. Intestinal tuberculosis was seen to be directly related to the type of disease present, that is, to the activity and progression of the disease, since in each sex group approximately 95 per cent of patients with fever had evidence of intestinal tuberculosis and in 88 per cent of those without fever this evidence was lacking. Using fever as a criterion, a degree of correct correlation between an elevated temperature and intestinal tuberculosis of 92.5 per cent was obtained. If those with a fever for two months or less were regarded as indeterminate, a correct correlation of 95.7 per

cent was obtained. Therefore a diagnosis of intestinal tuberculosis may be made, in spite of the absence of any other clinical sign or symptom, in those patients with pulmonary tuberculosis who have had a fever for more than two months.

Coccidioidal and Tuberculous Infections—The previous restriction of the parallelism of coccidioidal granuloma and tuberculosis to the reinfection type, Smith points out, has disclosed that the reinfection type constitutes only a fraction of infections, since in both diseases mild and even subclinical infections are the rule and serious disease is the exception. The principal port of entry of the two infections is the respiratory tract. The subsequent localization, pneumonitis, allergy and focalization of the primary infection are also similar. In both the result may be a walled off lesion which may calcify. The erythema nodosum of primary coccidioidomycosis, like that associated with primary tuberculosis, occurs soon after allergy is first established, when the patient is hypersensitive. It may possibly be a reaction of the extremely sensitive tissues to the circulating antigen. Postprimary erythema nodosum is rare in either disease. The pathogenesis of coccidioidal granuloma seems to be that of an endogenous reinfection. The primary infection not only does not predispose to the granuloma but actually confers a lasting immunity to exogenous infection. As in tuberculosis, the ability to focalize a coccidioidal infection seems to depend on some unknown quality of the host.

Fungous Infection of Lungs—After the primary invasion of *Coccidioides immitis*, Carter states that a number of patients, proportionally small but large in the aggregate, are destined to contract the serious secondary form, coccidioidal granuloma.

Primary involvement predominates in the female and does not appear to be related to race, social status or occupation. The secondary form has a definite predilection for male Mexicans, Negroes, Filipinos and Chinese, with occupations entailing special contact with the soil or its products. The secondary stage is essentially granulomatous with a tendency to abscess formation, while the acute progressive form is especially prone to widespread dissemination. The mortality is customarily stated as 50 per cent. Of the author's 113 patients, 56 per cent are dead. Roentgenograms of the chest were made in 99. Extrapulmonary manifestations were present in most. They consisted in enlargement of superficial lymph nodes, superficial or deep soft tissue abscesses, granulomatous nodules, ulcers or sinuses from adjacent infection in the skin, meningitis and lesions of bones and joints. Roentgenologically mediastinal adenopathy was the principal single manifestation in 70 of 92 cases in which intrathoracic involvement was present. Hilar involvement was a manifestation in 64 per cent occasionally without recognizable mediastinal enlargement. Only 19 patients had no evidence of hilar or mediastinal adenopathy. Frank parenchymal lesions occurred in several forms and were usually associated with some degree of mediastinal or hilar adenopathy. Thickening of the bronchovascular pattern as distinct from definite parenchymal infiltration, was frequent but difficult to evaluate. Diffusely scattered, irregular infiltrations "mottling" were present in 19 per cent. Indefinite cloudy zones were present in 37 per cent. Actual consolidations in 18 per cent, milky manifestations in 33 per cent. Scattered coarse nodular or hazy nodal foci in a few cases visible air containing cavities in 10 per cent. Fine linear shadows in 9 and coarse strand shadows in 14 per cent. Solitary, discrete nodal densities in 3 cases. Pleural exudate in 25 per cent. Lesions accentuated at or located in the apex or subapex in 50 per cent. An osseous lesion evident on the film of the chest in 25 per cent, and lymph node (9 per cent) or parenchymal (5 per cent) calcifications were not noticeably more frequent than would be true of a similar number of neutral chests from patients of the same class. It is not known how many of these may be residual from primary coccidioidomycosis. During an acute primary attack the roentgenogram of the chest may most closely resemble tuberculosis or pneumonia. The positive diagnosis still rests mainly on the identification of *Coccidioides immitis*.

Ludwig's Angina—Taffel and Harvey wish to dispel the myth that Ludwig's angina is a sinister affliction. They believe that the mortality will drop considerably when the disease is recognized early and is treated promptly and judiciously. At the New Haven Hospital over a period of twenty years 45 patients were treated for Ludwig's angina. Forty-six operations were performed on 43 patients and the infection of 2 subsided without operation after an abscess ruptured spontaneously through the floor of the mouth. There were 2 deaths, 1 of these patients had a dissecting aortic aneurysm which had suddenly ruptured into the thorax, and 1 had a concomitant suppurative cavernous sinus thrombophlebitis pulmonary abscess and pneumonia. The cardinal symptoms of the disease appear early and can be easily recognized. They include a tender swelling in the submandibular area of the neck, elevation of the tongue and edema of the floor of the mouth. The mortality is due not to some overpowering and occult virulence of the infecting organisms but more often to a mechanical obstruction of the respiratory pathway. The primary object of operation under local procaine hydrochloride anesthesia, is to relieve and to prevent the obstruction by releasing the tension within the submandibular space. This can be accomplished only by complete transection of the deep cervical fascia and the mylohyoid muscle, that is, a thorough decompressive procedure.

Whipple's Disease, or Intestinal Lipodystrophy—Pearse reports what he believes to be the seventh case of intestinal lipodystrophy. He states that it is the first case diagnosed during life, which made metabolic studies and observations on the effect of treatment possible. The true nature of the case was not established until Whipple examined the material removed at operation and made the diagnosis. Analytic data are presented which suggest that the abnormal fat digestion present in the disease is due to a fault in metabolism of bile salt. This view is strengthened by the clinical response of the patient to the administration of bile salt, but it cannot be proved until suitable analytic methods are available. However, this concept gives a working basis for the management of the disease.

Carotid Sinus Reflex—The various normal and abnormal activities of the carotid sinus reflex and the significance of the reflex in the field of surgery are reviewed by Ray and Stewart,

who state that, when the symptoms are mild or infrequent, reassurance, instruction in avoiding quick movements of the head or pressure on the neck and mild sedatives will often obviate or minimize attacks. Roentgen irradiation may be hazardous, as irradiation of tumors in this region sometimes induces a hypersensitive reflex. Prolonged use of atropine, ephedrine or other comparable drugs to control symptoms is not desirable. When symptoms are severe, surgical denervation of the carotid sinus is indicated. The normal carotid sinus reflex need not of itself be the source of serious complications during surgical procedures, but the fact that a hypersensitive reflex possesses potential dangers deserves wider recognition. It might be well to examine routinely the carotid sinus of every patient before operation. During operation, in the event of cardiac arrhythmia or asystole, bradycardia, vascular hypotension and possibly convulsions, infiltration of the area between the external and the internal carotid arteries with 1 per cent procaine on the side known to possess a hypersensitive sinus reflex will abolish the reflex and may possibly restore the patient. Simultaneous bilateral anesthetization is not advisable because bilateral laryngeal palsy may ensue.

*Use of Penicillin in Cultivation of *Acne Bacillus* S Craddock—p 558

Penicillin in Cultivation of *Acne Bacillus*—Studies were carried out by Craddock to see whether the *acne bacillus* was less sensitive to the bacteriostatic action of penicillin than was the *staphylococcus*. Pus from an *acne* pustule which contained both *acne bacilli* and *staphylococci* showed that it was less sensitive and that by using a concentration of penicillin which inhibited *staphylococci* a pure culture of *acne bacilli* could be obtained direct from an *acne* lesion. The simplest method of obtaining a primary pure culture from an *acne* lesion, whether or not it contains *staphylococci* as well as *acne bacilli*, is as follows. A tube of dextrose broth (pH 6.8) is boiled to expel dissolved gases. When this has cooled it is inoculated with pus from an *acne* lesion. Penicillin is then added so that the broth contains a concentration twice as great as had been previously shown to inhibit *staphylococci* growth. Hot sterile petrolatum is run on to the surface to a depth of $\frac{1}{4}$ to $\frac{1}{2}$ inch to exclude air. The tube is then incubated at 37 C for about sixty hours, when colonies of *acne bacilli* are perceptible, there is a copious growth in four days. In 47 cases a pure primary growth of *acne bacilli* was obtained in penicillin-dextrose broth, whereas in dextrose broth without penicillin when *staphylococci* were present they outgrew the *acne bacilli* and inhibited their growth. When the primary cultures of *acne bacilli* were plated anaerobically, two types of colony were observed. Type 1 gave a large heaped-up colony which was a yellowish buff and on blood agar was surrounded with a large zone of hemolysis. The individual bacilli were short, thick, irregular and often clubbed. Type 2 gave small flat colonies and the individual bacilli were longer, thinner and often curved. The two types often occurred in the same specimen of pus. In indolent pustules often seen in *acne*, type 2 bacilli were found in pure culture. Agglutination reactions in immune rabbits showed that the two types of bacillus were antigenically distinct.

Hazards of Transfusion—The hazards of blood transfusion, according to Whitby, are the systemic nonspecific pyrexial type of reaction due mainly to the apparatus and crystalloid

fluids used for transfusion, circulatory and vascular disasters due to the general condition of the recipient, intravascular hemolysis of the transfused blood and transmission of a disease from the donor to the recipient. Most of these hazards are avoidable. The pyrexial reaction with or without rigor can usually be eliminated by scrupulous cleanliness and technique. Experience and good clinical judgment reduce the incidence of circulatory disasters. Intravascular hemolysis from incompatibility will occur from time to time if a haphazard grouping technique is used. If the Landsteiner groups have been correctly determined, the risk of incompatibility is negligible at a first transfusion, but with multiple transfusions and with single or multiple transfusions to pregnant or puerperal women an elaborate direct grouping test and the simple biologic test should never be omitted. The danger of using the same donor for repeated transfusions to the same recipient now seems to be explained by the frequency of rhesus positive individuals who are potentially dangerous donors for multiple transfusions to a rhesus negative recipient. Homologous transfusion is the ideal and is preferred to the routine use of universal donors. There still remain a few reactions which particularly arise in patients with chronic illnesses although every care has been taken in grouping, these suggest that many subtle differences exist in the composition of human erythrocytes of which as yet there is no knowledge.

Iron Exchanges of Adults on White and Brown Bread Diets—Four men and 4 women took part in experiments on the iron exchanges on diets from which 40 to 50 per cent of the calories were derived from white or wheatmeal bread of 92 per cent extraction. There were ten periods of seven days on white and thirteen periods on diets on wheatmeal bread. Foods, urines and feces were sampled and ashed. The iron in the ashed food and fecal samples was estimated by the thioglycolic acid method (McCance, Widdowson and Shackleton, 1936) and the urinary samples by the thiocyanate method (McCance and Shipp, 1933). The menstrual losses of 3 of the women were characteristically different one from another but definitely constant for any 1 woman from month to month. Iron was absorbed from diets in which white bread constituted 40 to 50 per cent of the total calories, but it was not absorbed from similar diets with the wheatmeal bread. It is suggested that, in spite of the large amount of iron in whole wheat, bread made from such flour may not be as good a source of iron as it is generally supposed. Therefore, brown bread as a source of iron requires further investigation. Meanwhile Widdowson and McCance believe that it may be wiser not to lay too much stress on brown bread as a rich source of iron.

*Pathogenesis of Cooley's Anemia E Freudenberg and Margrit Esser—p. 128
Enuresis in Structure of Difficult Child K Heymann—p. 166

Pathogenesis of Cooley's Anemia—Freudenberg and Esser report 2 cases of Cooley's anemia occurring in brothers, aged 11 and 10, from the German part of Switzerland, they had no Italian blood. The authors emphasize that a strict racial latency is no more valid for Cooley's anemia than for the other forms of mutation anemia. So far, 10 cases have been described which did not belong to the Mediterranean race. The term "Mediterranean anemia" is therefore not justified. As Cooley himself supposed, there are forms of this anemia which pursue a mild course, the 2 reported cases corroborate this. Infectious conditions contribute to the manifestations of Cooley's anemia. The appearance of erythroblasts in the blood is a factor which greatly favors the appearance of Cooley's anemia. In 1 of the 2 reported cases the feces and the bladder bile contained greatly increased amounts of coproporphyrin. The protoporphyrin content of the erythrocytes apparently was increased in both. The bone marrow of both brothers contained numerous erythroblasts with red fluorescence, indicating the presence of porphyrin. The disturbance of the porphyrin metabolism is of particular importance in Cooley's anemia.

*Leukogranulocytopenia and Agranulocytosis from Use of Aminopyrine B Varela Fuentes R Canzani and A Navarro—p. 747

Angina Pectoris of Endocrine Origin—According to Fischer, anginal symptoms may be caused by endocrine disorders, such as thyroid insufficiency, hyperthyroidism, hypofunction or hyperfunction of the pancreatic islands, ovarian insufficiency and adrenal disorders. Myxedematous angina pectoris, as affected by thyroid therapy, presents four types: (1) myxedema with angina pectoris, both of which disappear on thyroid medication, (2) myxedema without angina in which the latter appears as a complication of the former when thyroid is given, (3) myxedema with angina, in which the latter is aggravated by thyroid therapy whereas the former is improved, (4) angina without myxedema, which disappears when myxedema appears. The fact that the cardiovascular system of patients with myxedematous angina pectoris of the first clinical type is normal suggests that the condition here is caused by reversible organic changes, namely interstitial edema of the myocardium with compression of the coronary arteries, infiltration of the heart with mucoid and reversible myxedematous enlargement of the heart. The pathogenesis of the second and third clinical types is analogous to that of angina in hyperthyroidism. Angina pectoris of the fourth type is due to certain forms of hyperthyroidism. Typical myxedema developing in these cases plays the role of a spontaneous thyroidectomy by which the angina is controlled. Angina pectoris is a frequent occurrence in hyperthyroidism. The anginal symptoms are frequently overshadowed by those due to hyperthyroidism. Angina in hyperthyroidism is the result of organic cardiovascular lesions. The therapy consists of a thyroidectomy which is indicated even in grave angina. The condition in diabetes is caused by changes in the coronaries. Pain is atypical. It does not yield to analgesics but is controlled by antidiabetic diet and insulin therapy. In angina pectoris of unknown etiology in obese patients with diabetes in the family it is advisable to make

blood sugar determinations. The type of angina in hypoglycemia depends on whether the latter is acute or chronic. Pain in acute hypoglycemia simulates an anginal attack of a myocardial infarct, in chronic hypoglycemia that of cardiac insufficiency. The electrocardiograms do not show coronary changes. Angina in a patient with blood sugar content of about 0.80 Gm per thousand cubic centimeters of blood should be regarded as of hyperglycemic origin. The diagnosis is supplemented by the history, the electrocardiogram and the dextrose therapeutic test. Menopausal angina pectoris caused by ovarian insufficiency is more or less typical. It should be differentiated from menopausal coronary angina. Menopausal angina of ovarian insufficiency and the electrocardiographic alteration regress on administration of estrogen. Angina due to adrenal disorders is especially observed in chromaphin adenoma and in Addison's disease. Pain in chromaphin adenoma is due to angiospasm. It diminishes and disappears as the symptoms of adenoma subside and disappear. Pain in Addison's disease is due to hypoglycemia.

Granulocytopenia from Aminopyrine—Varela Fuentes and his collaborators report that a woman aged 58 had been taking aminopyrine in large doses in the past for the control of neuralgic pain. The leukocyte count at the time was 2,200 with 44 per cent polymorphonuclear neutrophils. Discontinuation of the drug improved the leukocytic picture, which rose to 6,400 leukocytes with from 55 to 73 per cent polymorphonuclear neutrophils. With the improvement in the leukocytic picture pain diminished and almost disappeared. The bone marrow function continued to improve for one year when the patient developed pneumonia, in the course of which the leukocytes reached the figure of 17,200, with 87 per cent polymorphonuclear neutrophils. Two years later the patient had an attack of neuralgic pain, for which she took a preparation containing aminopyrine. Edema of the lips and acute agranulocytosis developed with a count of 1,200 leukocytes, with 0.5 per cent polymorphonuclear neutrophils and an ulcerative necrotic angina. For the last two years the leukocytic picture had been normal with figures varying from 4,250 to 7,100 and 48.5 to 69 per cent polymorphonuclear neutrophils. Intravenous injections of vitamin B₁ controlled the recurring pain.

Boletín de la Sociedad Cubana de Pediatría, Havana

14 113-168 (March) 1942 Partial Index

- Cholangiopathies in Children A Beguez Cesar—p. 113
Granular Follicular Conjunctivitis in Children R L Hernandez—p. 135
*Phimosis in Children A Carbonell Salazar—p. 148

Phimosis in Children—Carbonell Salazar reports 1,366 cases of congenital epithelial balanopreputial adhesions in infants, 22 cases of phimosis from balanopreputial adhesions in children and 265 cases of either atrophic or hypertrophic phimosis also in children. When the condition is uncomplicated a spontaneous cure takes place because of repeated erections. Local inflammation and infection from the adhesions are the cause of true phimosis. A simple method of treating adhesions in infants consists in drawing the prepuce back in order to free the glans. The epithelial cellular debris is wiped and liquid petrolatum is applied, after which the prepuce is allowed to return to its normal position. The procedure is repeated for five or seven consecutive days. Atrophic phimosis is due to disproportion between the diameters of the preputial ring and the glans. The treatment consists in dilating the ring with a two bladed dilator and in freeing the glans. If the preputial ring is resistant to instrumental dilation a simple incision is indicated. Hypertrophic phimosis is due to malformation of the preputial ring which is constituted not by the external and internal layers of the prepuce but by the hypertrophic preputial tissue. Circumcision is here indicated. The frenum should be liberated to secure a permanent result. The most frequent complications of phimosis in children are balanoposthitis and paraphimosis. In the author's cases manual, bloodless or simple instrumental procedures were resorted to in all but 40 in which circumcision was done.

Book Notices

Fundamentals of Anesthesia An Outline By Subcommittee on Anesthesia of National Research Council. Fabrikoid. Price \$2.50. Pp 217 with 72 illustrations. Chicago: American Medical Association Press 1942.

The Subcommittee on Anesthesia of the National Research Council realized that there was an urgent need for a book on the fundamentals of anesthesia at this particular time. The need was so urgent that finally it was decided that the three pamphlets issued by the American Medical Association in 1937, 1938 and 1939, dealing with the Scientific Exhibit sponsored by the American Medical Association should be the basis of the small book, which is now available.

Suggestions have been made concerning records. The fundamental physiologic considerations of the transport of oxygen and carbon dioxide in the body are discussed together with the necessity for aids in making the transport system function and the dangers that occur during anesthesia when the patency of the respiratory system is interfered with. Tables of the symptoms of oxygen want and the symptoms of excessive carbon dioxide are presented. The artificial airways are gone into in considerable detail.

Pharmacologic considerations are presented concerning the various agents consisting of the symptoms that they produce and the treatment to be used for poisoning with them. Tables show the physiologic and pharmacologic properties of inhalation agents and a list of drugs for topical, regional and spinal anesthesia, adjuvants used by anesthetists and sympathomimetic drugs used in combination with anesthetic agents. The signs of anesthesia are described.

Relief of pain is considered in the section on general anesthesia as well as oral and subcutaneous administration, rectal instillation, intravenous instillation and inhalation by both the open and the closed method. The carbon dioxide absorption technique is illustrated and described. Local anesthesia with procaine hydrochloride is described. Field block, infiltration, spinal anesthesia and various nerve blocks are briefly described and well illustrated. Topical applications of local anesthetics is discussed. Certain special techniques of analgesia are described. There is a special chapter on operations within the cranial cavity and another concerning anesthesia within the peritoneal cavity and within the pleural cavity.

The question of complications is discussed at some length in outline form. A chapter is devoted to respiratory emergencies to inhalation therapy and to circulatory emergencies and their treatment. Blood transfusion is discussed as well as the use of serum and plasma. The symptoms prophylaxis and treatment of heat cramps, heat exhaustion and sunstroke are presented. Convulsions are discussed, coma is presented, and poisoning from both the ordinary and special agents is presented in outline. War gases are named and discussed. Hazards, such as mistakes in writing prescriptions, in identifying patients or the site of operations and in identifying agents, are discussed. Accidents with compressed gases, accidental extravascular injections and the breaking of needles as well as fire and explosion hazards are presented.

Comfort and transport of the wounded are discussed. An appendix is presented giving information concerning compressed gases, how contents of cylinders may be measured, tables of equivalents, and composition of normal urine, normal blood, plasma and cerebrospinal fluid.

The book is indexed and a few pages have been left for notes. This book should be on the must list so far as the anesthetist is concerned.

Ornithologists of the United States Army Medical Corps. Thirty Six Biographies. By Edgar Erskine Hume. Colonel Medical Corps United States Army. With foreword by Alexander Wetmore. Assistant Secretary of the Smithsonian Institution. Washington D C. Cloth. Price \$5. Pp 583 with 110 illustrations. Baltimore: Johns Hopkins Press 1942.

Most American ornithologists are familiar with the names of Bendire, Cooper, Coues, Heerman and Mearns. Yet few, probably, except those physicians whose hobby is the avian fauna realize that these names belonged to men who were surgeons of the United States Army Medical Corps first and ornitholo-

gists but incidentally. As Colonel Hume explains in his introduction to the thirty-six biographies he has collected in this volume, the United States Army in its earlier days was a fighting force only, and when campaigns were not in progress the spare time of the medical officers was frequently used to the benefit of other branches of science than medicine.

Much of the work done by medicomilitary ornithologists in the fifth and sixth decades of the nineteenth century is said to have been inspired by Professor Baird (1823-1887) of the Smithsonian Institution. Baird married the daughter of Colonel Churchill, Inspector General of the Army, through whose influence he was said to have been able to secure the services of young medical officers as naturalists and surgeons of many of the railway and other expeditions in the West. As a result, much of the ornithological work of the Army medical officers is to be found in the ponderous tomes of the reports of these expeditions.

As an interesting sidelight it is worth noting that, because of the small size of the early United States Army and the insignificant number of medical officers, the rank of the Surgeon General was only that of Colonel. In fact, not until the administration of William Crawford Gorgas was the grade of Major General authorized for the Surgeon General.

In compiling this monograph, Dr. Hume states that he found it necessary to limit the biographic sketches to those of officers of the Regular Army, including acting assistant surgeons (contract surgeons). He admits that the temptation was great to include a number of prominent ornithologists who held emergency commissions in the Army of the United States during the first world war. But such an inclusion was not practical because there was no way of being sure of a complete list, to say nothing of the limitations of space.

Critical ornithologists may argue that the inclusion of at least one or two of the biographies is scarcely warranted by the facts. Surg. Gen. George Miller Sternberg, while a distinguished medical military man and an eminent bacteriologist, could hardly be classed as an ornithologist on no greater submitted evidence than his presidency for some years of the local Audubon society. So too with Leonard Wood, Surgeon and Major General, United States Army. Great man that he was, it seems stretching the facts to list him in a work of this sort as a medicomilitary ornithologist.

One other minor criticism of an otherwise splendid piece of work. The arrangement of the biographies alphabetically makes it less easy to follow the subject as a part of the history of medicine than would be the case if the chronological method had been used.

There are many interesting illustrations and an excellent index to enhance the value of the work.

A Symposium on Human Malaria with Special Reference to North America and the Caribbean Region. Edited by Forest Ray Moulton. Publication of the American Association for the Advancement of Science. No. 15. Publication Committee. Mark F. Boyd, Chairman. Cloth. Pp 309 with illustrations. Washington D C. The Association 1941.

This symposium which was held at the Philadelphia meeting of the American Association for the Advancement of Science, Dec 1, 1940 to Jan 1, 1941, comes to hand at a time when we are acutely aware of the importance of malaria not only as a public health problem but also because of its prime military significance in certain parts of the world. One needs but recall its contribution to the fall of American resistance on Bataan Peninsula. It is possible in the limits of this review to do little more than mention the topics considered.

The book opens with a historical introduction, and the rest of the material is divided under seven main headings. That on parasitology deals with the distribution of malaria in North America, Mexico, Central America and the West Indies; the taxonomy, morphology, life cycle, physiology and detection of the strains infecting man. The section on anopheline vectors has chapters on the general morphology, distribution, ecology and identification of Anopheles and classification of the nearctic species. There are discussions of the factors influencing infection of Anopheles with malarial parasites and the transmission of malaria by the anopheline mosquitoes of North America. The section on epidemiology deals with cyclical variation in the incidence of malaria in North America. The next section is

concerned with the symptomatology of infection in man due to the various strains of human malaria and also includes a discussion of blackwater fever. The section on pathology and immunity contains chapters on some pathologic aspects of human malaria, the physiologic pathology of malaria, characteristics of immunity, the cellular basis for immunity in malaria and humoral immunity in malaria. The section on treatment considers cinchona and its alkaloids, antimalarials other than quinine, experimental chemotherapy and a summary of ten years of observations on malaria in Panama with reference to control with quinine, atabrine and plasmochin, without anti-mosquito measures. The section on control and eradication contains articles on general considerations in planning malaria control methods and procedures in malaria survey, methods directed against adult mosquitos, housing, drainage and filling methods, the management of water, petroleum products for mosquito control, paris green and other stomach poisons as larvicides against mosquito larvae, naturalistic methods of malaria control, adaptability of control measures to the nearctic fauna of Anopheles mosquitoes, the adaptability of control measures to the malaria vectors of the Caribbean region and the antimalaria program in North America.

As might be expected, the quality of these articles is not uniform. Many of them are written by recognized leaders in the particular fields. It is to be regretted that so much space is devoted to elementary information and considerations which can be found in most textbooks devoted to the subject. The sections dealing with the anopheline vectors, pathology, immunity and treatment are particularly informative. From the point of view of one who is interested in the mechanisms of infection, the section on pathology and immunity is an excellent survey of the recent work in this field and is far ahead of the usual textbook discussions of the problems involved. A serious lack in the book is its restriction to human malaria, which eliminates to a large extent serious consideration of much of the extensive and exceedingly important experimental work which has been done on other hosts, particularly the birds. At the end of the volume is a fairly comprehensive bibliography, which serves for all the articles.

A Textbook of Surgery By American Authors Edited by Frederick Christopher B.S. M.D. F.A.C.S. Associate Professor of Surgery Northwestern University Medical School Chicago Third edition Cloth Price \$10 Pp 1764 with 1538 illustrations Philadelphia & London W.B. Saunders Company 1942

This popular textbook of surgery has been completely revised and reset. It contains forty chapters written by one hundred and ninety-five American authors, the material having been assembled under the editorial direction of Frederick Christopher. The book is attractively bound and is exceptionally well illustrated and indexed. Following the customary form, the introductory chapters are concerned with wounds, inflammation, tissue repair and injuries due to physical and chemical agents. These are followed by sections devoted to regional surgery. The specialties of neurosurgery, orthopedics, genitourinary surgery, otolaryngology and gynecology are allotted space commensurate with their importance to the general surgeon. This arrangement adds completeness to the work, which is intended to embrace the field of surgery as a whole. Because of the greatly increased interest in the subject of trauma at the present time and since graduating students are expected to be reasonably familiar with the problems of military surgery, the sections on fractures, dislocations and amputations are of special value. A timely addition is a new chapter on war injuries by R. I. Harris of Toronto. The chapter on diseases of the gallbladder and bile ducts, originally written by the late E. Starr Judd, has been thoroughly revised and brought up to date by Howard K. Gray. This includes a discussion of prothrombin clotting time, vitamin K therapy and cholangiography. The section on gastric ulcer has been taken over by Cutler, Zollinger and Bailey and reflects the latest thought on the management of this important lesion. The descriptive material is well elucidated by sketches by Miss Mildred Codding. Other new chapters include (1) diseases of the thymus gland by Alfred Blalock, (2) coccidioidal granuloma by Hiram E. Miller and (3) anal pruritus and hemorrhoids by Newton D. Smith. A convenient bibliography of the more important articles pertaining to the subject is appended to each chapter.

In spite of the rapid pace at which surgical knowledge accumulates, the book presents the most recent information on such matters as the general and topical use of the sulfonamide drugs, surgical treatment of patent ductus arteriosus, Beck's operation for coronary artery disease, the use of heparin internal fixation for fractures of the neck of the femur, sympathectomy for hypertension and the management of postoperative pulmonary atelectasis.

Since the present trend in the undergraduate teaching of surgery is toward more clinical and less didactic instruction, the student of today must necessarily rely for much of his information on outside reading. Whether the ideal textbook for this purpose is one written for the most part by a single author or is one in which the various subjects are discussed by many men, each a well known specialist and authority in his particular field, is a matter of opinion. If the latter type of textbook is to serve its best purpose, the material must be carefully integrated and edited in order to maintain a proper balance and to avoid undue emphasis on highly specialized subjects. That this has been successfully accomplished by Christopher is apparent from even the most cursory inspection. The work is probably the most complete treatise on surgery today available in a single volume, and yet in spite of its large scope the book remains readable and has not assumed unwieldy proportions. It is a work which is the logical successor of DaCosta's Surgery, which for so many years held a unique place among medical textbooks, and it should prove to be of the utmost value not only to the student but to the house officer and the busy practitioner as well.

Plastic Surgery of the Breast and Abdominal Wall By Max Thorek M.D. LL.D. F.I.C.S. Professor of Surgery Cook County Graduate School of Medicine Chicago With an introduction by Rudolf Nissen M.D. F.I.C.S. With a foreword by J. Eastman Sheehan M.D. F.I.C.S. Professor of Plastic Reparatve Surgery New York Polytechnic New York Cloth Price \$16.50 Pp 446 with 458 illustrations Springfield Illinois & Baltimore Charles C. Thomas 1942

This is no doubt the first book devoted exclusively to this subject. Many books have been written on plastic surgery of the face and extremities, but few volumes have been concerned with the breasts and with the removal of excessive fat. Advances in surgical technic have tended to expand the borders of plastic reparative surgery. Certainly any procedure which will aid to control hypertrophied breasts so as to affect the woman concerned mentally, physiologically and physically and thus to permit her a new life must be considered warranted. The book by Dr. Thorek is a complete consideration of the subject, including history, anatomy, anthropology, etiology, pathology, surgical indications and contraindications and technic. Sixteen chapters are devoted to the breasts, and one large chapter to reconstructive surgery of the abdominal wall. The book is based on an extensive experience. It is magnificently illustrated and deserves special recognition as a pioneer in its field.

The History and Evolution of Surgical Instruments By Dr. C. J. S. Thompson With a foreword by Dr. Chauncey D. Leake Cloth Price \$8.50 Pp 113 with 115 illustrations New York Schuman's 1942

Prof. C. J. S. Thompson is widely known as the curator of the Royal College of Surgeons in Great Britain. Much of the material in this book has previously appeared in the *British Journal of Surgery*. The volume traces the development of all the common surgical devices from the scalpel to the operating table. It is well illustrated, beautifully printed, and should make a fine gift volume for any surgeon.

Rabies By Leslie T. Webster M.D. Cloth Price \$1.75 Pp 168 with 8 illustrations New York Macmillan Company 1942

Knowledge of rabies has advanced considerably in recent years, but the application of that knowledge is still delayed as evidenced by the fact that rabies has increased in some sections of the United States. The author presents a critical and fairly inclusive consideration of the subject, covering the diagnosis and prevention of rabies. In an appendix information is supplied concerning the disposal of rabid dogs, the licensing of dogs, quarantine, immunization and similar problems. There is also an excellent bibliography and index.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BLISTERS ON FEET AND COMPOSITION OF SHOES

To the Editor—The U. S. Army has been resoling shoes with a rubber composition. This results in a certain number of men developing blisters while in the garrison and on the march as well as definite edema. This office would like to know the percentage of people who are sensitive to rubber, the percentage of people who are sensitive to wool, the percentage of people who are sensitive to cotton, the percentage of people who are sensitive to leather and whether the glue used to hold the soles may be involved in this sensitivity.

George H. Wood, M.D.
Captain, M. C. U. S. Army
Fort Leonard Wood, Missouri

ANSWER—The percentage of people sensitive to pure raw rubber itself (latex) is exceedingly low. However, there is a considerable percentage of people sensitive to the compounds placed into rubber in order to make it serviceable. The accelerators and antioxidants used in rubber are the chief sensitizers. In a recent series of experiments with certain reclaimed rubber from six different manufacturers it was possible to sensitize from 2 to 20 per cent of 213 persons given patch tests (Schwartz, Louis, and Tulipan, *Louis A. Textbook of Occupational Diseases of the Skin*, Philadelphia, Lea & Febiger, 1939, pp. 386-388).

There are no statistics available as to the percentage of people sensitive to wool. It must again be remembered that wool as worn in clothing is not the same as the wool when it comes off the sheep. It is processed with mordants, dyes, oils and finishes, and sensitivity may be induced by any one of these chemicals and not by the wool itself. Despite these facts, it must be borne in mind that millions of people wear processed wool, and the cases of wool sensitivity reported are few and far between (Schwartz and Tulipan, pp. 220-227).

What has been said concerning wool also applies to cotton. There are no available statistics as to people sensitive to leather. But it again must be borne in mind that leather is a complex product. Hides must be unhaired, tanned, dyed, oiled and similarly treated before they become leather, and any of these chemicals may be retained in the leather and cause sensitization. The dyes and the tanning agents are the principal causes of dermatitis from leather (Schwartz and Tulipan, pp. 323 to 325).

It is difficult to see how the glue used to hold the soles can be implicated as the cause of the blisters on the feet, because the glue would have to go through the insole, the shoe lining and the socks in order to touch the feet.

The fact that a certain number of marching men develop blisters does not necessarily incriminate the rubber composition used for resoling the shoes. It must be borne in mind that the soles of the shoes do not touch the skin. There are inner soles and shoe linings and stockings in between the sole and the skin. It is much more likely that the blisters and edema would be caused by dermatophytosis activated by the perspiration of the feet due to marching. The blisters could also be caused by the friction of shoes and stockings (Schwartz and Tulipan, pp. 561 and 611).

SURGICAL PROCEDURE FOR BRONCHIAL ASTHMA

To the Editor—Has any surgical procedure ever been tried for the relief of intractable asthma?

Norman P. Rindge, M.D., Clinton, Conn.

ANSWER—Two surgical procedures have been recommended for the treatment of bronchial asthma. Kummell in 1923 and 1927 reported favorable results from unilateral sympathectomy for bronchial asthma. Gobell in 1928 and Leriche and Fontaine in 1939 also reported favorable results. However, similar operations by other surgeons have been complete failures. Phillips and Scott in 1929 and Riehoff and Gay in 1938 reported bilateral resection of the vagal connections with the posterior pulmonary plexus. This procedure seems, from a physiologic point of view, to be preferable to sympathectomy.

The inconstant results obtained by upper thoracic sympathetic ganglionectomy casts grave doubt on this procedure. Section of the pulmonary vagal branches apparently has given excellent results in some cases, but too few operations have been performed to pass final judgment as to its value.

SURGICAL TREATMENT FOR CHRONIC MAXILLARY SINUSITIS

To the Editor—What is the present status of operative treatment of chronic suppurative maxillary sinusitis?

Robert E. Cloud, M.D., Ensley, Birmingham, Ala.

ANSWER—There is no single or simple answer to this query. Given a case of chronic suppurative maxillary sinusitis and assuming that all the simple and nonoperative procedures have been given a fair trial over a sufficient period, the choice of operative procedure on the sinus itself will lie chiefly between the window operation or intranasal antrostomy and the Caldwell-Luc operation, which is carried out by a sublabial approach. The latter intervention has some modifications highly praised by a smaller number of surgeons who practice them in the form of the so-called Denker operation and the intranasal form of the latter perfected by Canfield. In general the intranasal antrostomy, which fell into disfavor for a while because of a tendency for the window to close, has regained popularity by improvements in technique. In its favor, among other things, are ease of performance and less reaction.

The Caldwell-Luc or canine fossa approach has its adherents, who claim for it better opportunity for inspection of the antral contents and easier removal of diseased mucosa. This type of operation is more likely to produce local and general reactions, is harder to do and calls for a lengthier convalescence. Many rhinologists are therefore apt to feel that a well conducted window type of operation should be tried first and converted later on if necessary in the small number of failures into the Caldwell-Luc type of intervention. The proponents of each of these types of operation are clinicians of standing and can be trusted when they say that they get a surprisingly large number of cures, more or less permanent.

HABITUAL ABORTION

To the Editor—A healthy primipara aged 35, whose serologic reaction and other laboratory work are normal, has miscarried at six months twice within the last eighteen months. The first time she noticed a milky vaginal discharge and felt that the fetus was down too low in the pelvis. On examination it was found that the cervix was already dilated about 2 inches and that the membrane was protruding. Elevation of the foot of the bed, complete rest in bed and narcotics failed to stop the process. The next time her cervix simply got soft, dilated and after dilatation of about 2 finger breadths she was put to bed. The foot of the bed was elevated, progesterone was given intramuscularly, vitamin E was administered, and after she had stayed in bed one month the bag of waters ruptured and she miscarried again at six months. She doesn't have pains until the cervix is fairly well dilated, and there is no bloody discharge when the cervix first dilates. In fact the bloody discharge does not occur until she is having fairly hard pains. Following the last miscarriage multiple punctures of the cervix paralleling the axis of the cervical canal were made with a high frequency needle, the object being to cause a deposition of fibrous tissue in the cervix. Would it be advisable for the patient to become pregnant again and what, if anything, can be done to prevent the miscarriages? I feel that they are due to softening of the cervical portion of the uterus with a consequent inability of the uterus to hold the fetus.

M.D., Texas

ANSWER—Habitual abortion occurring near the period of viability is an unsatisfactory condition to treat. Careful physical and pelvic examinations often reveal a complete absence of any pathologic factor that could predispose to an early termination of a pregnancy. The state of the cervix is rarely the primary cause for the onset of premature labor. At the present state of our knowledge a failure of the endocrinal mechanism is the most apparent cause for the premature interruption of the pregnancy.

The patient should be encouraged to make another attempt. Prior to conception she should have a complete examination including a basal metabolism determination. Treatment should be instituted immediately after the missed menstrual period. The patient should receive thyroid in liberal amounts. A good rule to follow is to give 0.065 Gm (1 grain) a day when the basal metabolic reading is 0 to -10, 0.13 Gm (2 grains) a day between -10 and -20 and 0.2 Gm (3 grains) a day between -20 and -30. She should receive vitamin E in the form of mixed tocopherols, a 50 mg capsule twice daily. Moderate amounts of progesterone, from 1 to 5 mg in oil, can be given three or four times a week and perhaps daily during the missed menstrual days. All stimuli should be avoided. Coitus, cathartics and douches are contraindicated. The advisability of rest in bed is an open question but it can do no harm and it may be of value during the missed menstrual periods. These measures should be continued until the fetus is viable. This empirical regimen has as yet little scientific background but in the absence of accurate knowledge concerning the cause of the condition more rational treatment cannot be recommended. Many clinical reports in the literature confirm the value of this empirical treatment.

PARATHYROID TETANY AND PREGNANCY

To the Editor—A woman aged 28 had a thyroidectomy six years ago. Since that time it has been necessary for her to take 80 grains (5.2 Gm) of calcium lactate daily with some form of vitamin D. Otherwise she is in good health. If pregnancy should occur what would be the effects of calcium metabolism on her and the fetus? How should she be managed what would be the effect of solution of parathyroid? Several times tetany occurred when oral calcium was discontinued for several days.
M D Illinois

ANSWER—A woman with parathyroid tetany may be carried through pregnancy without complications. The fact that tetany has occurred several times when the administration of calcium was discontinued shows that the patient still has hypoparathyroidism. The treatment of parathyroid tetany is the same during pregnancy as when pregnancy is not present. The most important thing is to maintain the serum calcium at about the normal level.

The best way to do this is to administer large doses of calcium by mouth and supplement it with dihydrotachysterol or concentrated vitamin D₂. The dose of calcium now being administered, namely 80 grains of calcium lactate daily, should be sufficient. The usual maintenance dose of dihydrotachysterol varies from 1 to 4 cc a week, and the dose of vitamin D₂ that is commonly used is 50,000 U S P units daily. Solution of parathyroid does not play a very important part in the treatment of tetany. Its effectiveness diminishes with continued therapy, so that the dose must gradually be increased to an extremely high level. This makes the material both expensive and unsatisfactory. However, there is no difficulty in controlling tetany with the measures outlined.

Pregnancy has been observed in a patient with parathyroid tetany, and so far as could be noted the offspring was just as normal as if the mother had not had tetany, and no untoward effects were noted in the mother as a result of the pregnancy.

GLOSSITIS IN YOUNG CHILD

To the Editor—A boy aged 3 years has had glossitis since he was about 8 months of age. It seems to develop periodically in conjunction with a great deal of mucus with the stool. The parent can give no specific time when it develops except anywhere from every two to three weeks to a month. At these particular times the tongue becomes sore and the child has difficulty in eating. The appearance of the lesion seems to take the form of patches the edges slightly raised and white as of mucus while the centers of each patch become red and inflamed. I never find it to spread to the buccal mucous membranes or to the throat. The Wassermann reaction is negative. The child at one time was treated for pinworms but no evidence has been noted of parasites for some time. The mother states that in the past when the tongue became too sore application of mild protein silver 20 per cent seemed to relieve it somewhat but that it never cured the condition.

Walter A. Bray M.D., North Stratford N.H.

ANSWER—The glossitis may be due to a local infection, may occur as a result of a deficiency or may reflect the condition of some lower part of the intestinal tract.

To help complete the information, one would have to rule out (by repeated stool examination) a continued infestation, know whether the gastrointestinal tract was normal by a barium sulfate and x-ray series, know whether the abdomen or the liver was enlarged, and know how the child tolerated food, how his nutrition is at present and whether steatorrhea has been present. A complete blood count and bacteriologic studies of the mouth flora would be valuable. Blood vitamin levels may be hard to obtain, but determination of A and C would help decide, by inference, the amount of B present.

The best diagnosis from the evidence given would seem to be celiac disease. It may be present at 8 months of age, it may produce mucus in the stools and it can cause vitamin and other deficiencies by faulty absorption. A trial of high protein diet, excess vitamins (especially B complex) and the use of pancreatic extracts (though this is not invariably thought valuable) would be worth while. The use of iron or an iron and liver extract combination would depend on the results of the blood count.

MENINGOCOCCUS CARRIERS

To the Editor—In the case of contacts of a meningitis case is it worth while taking nose and throat cultures or will the incidence of positive cultures usually be found high in these contacts and therefore of little help in determining which case should be isolated as positive contacts?

Horace L. Wolf M.D., San Diego Calif.

ANSWER—The inquirer has supplied his own answer regarding the search for carriers of meningococci among contacts. There seems to be no value in such a procedure except for academic interest. Should meningitis develop in a carrier who is under medical control, it can be promptly cured in the majority of cases with appropriate sulfonamide drugs.

REFRACTORY URINARY FREQUENCY IN YOUNG GIRL

To the Editor—A white girl aged 16 unmarried has a negative past history except for ordinary diseases of childhood. She had a moderately severe attack of influenza one year ago no complications and uneventful recovery. Immediately after her recovery frequency of micturition developed—no pain no burning no straining either before or after micturition—only frequent desire to go (twelve to twenty times in twenty-four hours). The urine has been normal from the beginning of the trouble. The twenty-four hour output is only slightly in excess of normal (2½ to 3¼ pints). There are positively no constitutional or local symptoms other than the ordinary sensation of desire. The mother states that a urologist said the roentgenogram showed a black spot on one kidney but he never showed her the picture. She presents no symptoms of cystitis other than the frequency. For the past five months she has been receiving bladder instillations but is gradually getting worse. The girl and her mother are desperate. It is a humiliating situation. The girl feels that she is an object of ridicule because during school hours she has to go to the toilet so often. She has become extremely self-conscious and is practically self-ostracized from all student activities and social functions. Now here is a peculiar sidelight over the week ends when not in school she is usually nearly if not altogether free of symptoms. That leads me to think that there must be a large psychic factor involved. If from my rather inadequate description of the case you concur in that opinion what would you suggest in the way of management and treatment? Last week in order to see what the results would be I took her out of school and she cried as if her heart would break because she is an honor student and wants to graduate. Any suggestions you might be able to offer would be deeply appreciated.
M D Ohio

ANSWER—The essential problem in this case is the differential diagnosis of urinary frequency. It is desirable to exclude organic disease before concluding that the symptoms are of functional nature. The normal urinary output would tend to exclude diabetes insipidus, high specific gravity of the urine would be further evidence against diabetes insipidus. The absence of glycosuria would exclude diabetes mellitus as the cause of the urinary frequency.

Atypical interstitial cystitis may manifest itself as simple urinary frequency, without pain and with asymptomatic periods. It is frequently difficult to make a diagnosis of interstitial cystitis, and competent specialists will admit that they have overlooked such cases. The negative urinalysis would be in keeping with such a diagnosis. All other forms of cystitis are usually accompanied by the presence of pathologic elements in the urine. Nonspecific chronic urethritis may produce simple urinary frequency.

It would seem advisable to consider that this patient has interstitial cystitis and the following treatment may be considered: solutions of silver nitrate, of increasing strength, instilled into the bladder daily. The initial concentration should be 1:3,000 and the concentration increased to 1:100 during the following two weeks. The solution should be instilled into the bladder through a catheter, permitted to remain in place for five minutes and then drained off with the catheter. When higher concentrations are employed it may be necessary to prescribe opiates to relieve the temporary pain.

If urinary frequency persists, attention should then be directed toward the urethra. Tampons of strong protein silver solution (5 per cent) inserted into the urethra will frequently be efficacious. Dilatation of the urethra to 24 French with massage of the urethra about the sound may help.

If symptoms persist in spite of these treatments it will be necessary to repeat the urologic investigation, both excretory urography and cystoscopy should be carried out. It is impossible to surmise what the urologist intended to convey by the expression "black spot."

If the urologic investigation reveals no abnormalities, the urinary frequency must be considered as functional in nature and treated by means of rest, recreation, suitable hobbies and mild sedation.

INHERITANCE OF BLOOD GROUPS

To the Editor—Does a child always have the same type blood as its parents? For instance if the father was IV and the mother IV, would the child be anything except type IV?

Joseph Holton M.D., Sarasota, Fla.

ANSWER—The child does not always have the same blood group as its parents. The laws of inheritance are that 1 The agglutinogens A or B cannot appear in the blood of a child unless present in the blood of one or both parents. 2 The combinations group AB parent with group O child, and group O parent with group AB child are not possible, regardless of what group the other parent belongs to. For example, in families where the two parents belong to group O and group AB respectively, half the children will belong to group A and half to group B, so that none of the children will have the group of either parent. Incidentally, if one designates the groups by numbers, as the inquirer does, one would have I by IV, giving

II and III This confusing result is one reason why the designations of the groups by numbers should never be used, besides, two methods of designating groups by numbers exist. The inquirer does not state which designation he uses. Finally it should be pointed out that in cases of disputed parentage tests should be made not only for the blood groups but also for the M-N types, in order to get the maximum information. For further details the books by Wiener (Blood Groups and Blood Transfusion, Springfield, Ill., Charles C. Thomas, 1939) and Schiff and Boyd (Blood Grouping Technique, Interscience Press, 1942), should be consulted.

EXCESSIVE SOMNOLENCE AND ENURESIS IN ADULT MAN—RESISTANT VAGINITIS IN YOUNG GIRL

To the Editor—A white man aged 32 has been suffering from enuresis since childhood. For the past twelve years he has not missed a single night wetting the bed. One hour after falling asleep the first bed wetting occurs, and this may be repeated two or three times during the night. His sleep is profound, no alarm clock is powerful enough to awaken him in the morning. His wife must throw him off the bed and slap him to get him up each morning. He is 5 feet 11 inches (180 cm.) in height and weighs 200 pounds (91 Kg.). His blood pressure is 120 systolic and 80 diastolic. The heart and lungs are essentially normal. The serologic reaction is negative and the urinalysis is normal. The reflexes are normal. Cystoscopic examination is negative although several cauterizations of the verumontanum were done. The prostate is normal. Roentgenograms of the kidneys and ureters are negative. All sorts of medications including atropine derivatives have been given to no avail. He smokes two packs of cigarettes a day and cannot break the habit. Have you any suggestions as to the diagnosis and treatment? During the day he feels just as normal as any one else. Is the profound somnolence at night a factor in the enuresis? What measures can be taken to control it? Is there any drug that can lighten his sleep so that he will be able to arise easily in the morning? He has a daughter aged 8 who is suffering from a stubborn vaginitis nonspecific in nature which is also resistant to treatment. The sulfonamides and vaginal irrigations are of no avail. What is a good therapeutic regimen for the cure of this nonspecific vaginitis when sulfonamides and mild protein silver and mercurochrome solution irrigations are of no avail? Will the estragens help?

M. D. New York

ANSWER—It is possible that the profound somnolence which the patient has at night may be a factor in his enuresis. There is no drug available that will lighten his sleep. Since the patient has had a complete urologic work-up and nothing could be found to explain the enuresis it would seem advisable for him to be examined by a neurologist. From the history and findings submitted it would be extremely hazardous to venture a diagnosis.

With regard to the patient's 8 year old daughter who is suffering from a stubborn vaginitis an examination of the vagina should be made, if it has not already been done with a small speculum to rule out the possibility of a foreign body. In many little girls with nonspecific vaginitis there is a tendency to overtreatment, which keeps the irritation active. Sometimes when treatment is discontinued the condition clears up. It is not stated whether the sulfonamides were given by mouth or a solution or an ointment used. If a solution has not been used, the vagina could be irrigated twice a week with one-half ounce of 5 per cent sulfathiazole solution.

POSSIBLE PITIRIASIS LICHENOIDES

To the Editor—For about two years a man aged 28 has had great numbers of dark red macules and papules the size of sweet pea seeds which are more numerous on the chest, abdomen and back but are distributed to all areas excepting the face, hands and feet. They are not tender or slightly itchy and appear more numerous following a hot bath and rub while a few may be blanched with pressure. He is a motor mechanic athletic in type and has had no illness excepting appendicitis which was relieved by surgery. The only other complaint at present is aspermia with sterility. Repeated blood Wassermann tests have been negative and the blood calcium is normal. He has had large quantities of vitamins a series of treatments of iron and arsenic intramuscularly and a prolonged course of bismuth subsalicylate but the results have been nil. Please give an opinion on diagnosis and treatment.

Ewart S. Sarvis, M.D., Sumas, Wash.

ANSWER—From the meager description given, the possibility of the condition being pityriasis lichenoides chronica must be considered. This condition belongs to the parapsoriasis group and consists of a generalized eruption simulating psoriasis. To aid in diagnosis a biopsy is suggested, and the material should be submitted for study to a competent histopathologist. Treatment, as a rule, is not satisfactory in the chronic forms of parapsoriasis and consists in tonic measures together with generalized ultraviolet ray exposures. The possibility that pityriasis lichenoides chronica may presage the premalignant stage of granuloma fungoides (lymphoblastoma) must be considered, and the study of new cutaneous lesions that appear together with blood studies are of value in determining this.

OBESITY AND PROBABLE MIXED GLANDULAR DEFICIENCY IN YOUNG GIRL

To the Editor—I would appreciate having some advice on the treatment of a girl aged 16 who weighs 195 pounds (88.5 Kg.), is about 5 feet 1 inch (155 cm.) in height and shows obesity much like the adiposity of her mother. She has a mild headache, some disturbance of vision with myopia and astigmatism and the menses are irregular having started when she was 11 years of age and since then she has had only six week periods. She has a strong craving for salt. She was good at school until this year when she slipped slightly in her studies. Her fat is distributed all over the body except that her legs and forearms are not fat as compared with the rest of the body. Her breasts are large and heavy and appear to drop a good deal. The urine shows a trace of sugar but her blood sugar is 126 mg. per hundred cubic centimeters. Her blood picture is normal and the basal metabolism is a minus 32.

M. D., Oregon

ANSWER—The history suggests the diagnosis of hypopituitarism with secondary hypothyroidism and secondary hypogonadism.

In order to be certain that hypothyroidism is not the only abnormality involved it would be well to raise the metabolism to normal with desiccated thyroid at the same time that a suitable weight reducing diet is given. If the menstrual irregularity does not clear up with this therapy, the effect of equine gonadotropin may be tried in a dose of 400 international units given daily for ten days after cessation of menstruation. This should be repeated after each succeeding menstrual period. If this therapy fails to correct the menstrual irregularity, substitution therapy with estrogenic substance may be tried for a period of two months, giving 10,000 rat units of alpha-estradiol benzoate once a week except during the time of the menstrual period.

In view of the headache it would be well to rule out a pituitary tumor with a roentgenogram of the sella turcica.

EFFECT OF SINGLE LARGE ALCOHOL INTAKE ON FETUS

To the Editor—A patient is worried about the effects of alcohol when taken early during pregnancy on the future child. Specifically this woman drank about 36 ounces of beer shortly after conception and before she knew she was pregnant. What is the present opinion in this respect as to imbibing that amount of alcohol on only one occasion early in pregnancy?

M. D. New Jersey

ANSWER—The patient need have no worries about the effect of her beer debauch on her unborn baby. The amount of alcohol even in 36 ounces of beer is scarcely large enough to injure a fertilized ovum. In fact in human beings it is difficult to prove that alcohol has a deleterious effect on babies in utero even when large amounts are taken. Vignes (*Revue anthropologique* 51:33 [April-June] 1941) maintains that acute alcoholism is a frequent cause of congenital defects, but whereas this is true among animals it has not been definitely proved for human beings. Likewise Vignes believes that acute alcoholism favors premature interruption of pregnancy.

PROBABLE SUBUNGUAL GLOMUS TUMOR

To the Editor—A patient has a small faintly pigmented area underneath a fingernail which produces exquisite pain on pressure. My diagnosis is subungual pigmented neuroma for which I have advised excision of the nail and destruction of the lesion with the cautery. Is this correct procedure?

M. D. Indiana

ANSWER—The scanty information supplied suggests that the subungual lesion may be a glomus tumor. A favorite site for a glomus tumor is beneath the fingernail. These tumors are small, match head size or larger lesions, soft or firm, bluish red and very painful. In some cases the pain is agonizing and radiates from the finger toward the shoulder. Pain is increased by a change in temperature, particularly cold. These tumors do not metastasize and seldom recur. Treatment consists in surgical excision.

TYPHOID VACCINATION IN THE UNITED STATES ARMY

In reply to an inquiry published in *Queries and Minor Notes*, June 27, 1942, page 763, under the heading "Intradermal Injections of Diphtheria and Typhoid Vaccines," it was stated that the United States Army gives one injection of 0.1 cc. of typhoid vaccine intradermally in routine reimmunizations. This method of reimmunization has received careful study at the Army Medical School, Washington, D. C. For various reasons it has not been officially adopted for routine use in the Army. Routine reimmunizations are now accomplished by three subcutaneous doses of triple typhoid vaccine.

RENAL PATHOLOGIC CHANGES IN HYPERTENSION AND GLOMERULONEPHRITIS

CLINICAL INTERPRETATION

CHAIRMAN'S ADDRESS

J P SIMONDS, MD
CHICAGO

Much of the very abundant literature on diseases of the kidneys during the past five years has consisted in reports of clinical investigations of renal function in nephritis and hypertension as revealed by inulin and diodrast clearance tests. These two substances possess certain qualities that render them particularly useful for this purpose, and these tests appear to rest on a theoretically sound basis. The object of most of these investigations has been to measure the degree of competence of the kidneys to perform their function of elimination and to formulate a concept of the conditions that must exist in these organs in order to give rise to the observed results of these tests. There are few or no available observations based on a comparison of the actual pathologic changes in the kidneys and inulin and diodrast clearances. It is my object in this paper to reverse this clinical point of view and to interpret the pathologic changes characteristic of nephritis and hypertension in terms of the inevitable effects of these structural alterations on the general functional capacity of the kidneys.

To attain this end it is necessary to have clear concepts (1) of the normal structural pattern of the kidneys, (2) of the mechanisms by which the kidneys perform their functions through the medium of this structural pattern and (3) of the basic changes induced in this structural pattern by disease. By integrating these three concepts, one can interpret the effects of these structural alterations on the normal mechanisms of the kidneys and the disturbances of renal function in nephritis and hypertension.

STRUCTURE AND FUNCTIONS OF THE KIDNEYS

Each human kidney contains approximately one million anatomic and physiologic units or nephrons. Each nephron consists of a glomerulus and a tubule. The glomerulus is a tuft of nonanastomosing capillaries, lined with ordinary endothelium and covered externally with a single layer of very thin epithelial cells. This

mass, which forms an ideal semipermeable membrane or biologic filter, is invaginated into the upper end of the tubular portion of the nephron.

Each renal tubule is divided into four portions. The proximal convoluted tubule follows a tortuous course in the cortex of which it forms a considerable portion. Its function is the conservation by selective reabsorption from the glomerular filtrate of substances needed by the body. This process requires the simultaneous "obligate" reabsorption of a volume of water that is proportional to the quantity of solute (sugar, urea, chlorides) absorbed. The distal convoluted tubule also lies in the cortex and its chief function appears to be that of altering the reaction of the urine and rendering it relatively strongly acid. Intercalated between the proximal and distal convoluted tubules is Henle's loop. This structure is peculiar to the kidneys of birds and mammals, the only animals that are capable of secreting a urine that is hypertonic to the blood. Henle's loop concentrates the urine by the "facultative" absorption of water. The collecting tubules, in which the distal convoluted tubules end, are mere conduits without specific function except that of conducting the finished urine to the renal pelvis, whence it passes to the bladder for final excretion.

It is a general biologic principle that the structural pattern of the circulation in such organs as the liver, lungs and kidneys, which are concerned with producing changes in the composition of the blood, is quite different in principle from that in other organs, such as the brain and heart muscle, in which the blood supply is only for nourishment and the removal of waste products. In accordance with this principle the blood supply of the kidneys not only is very abundant but possesses certain peculiarities that differentiate it from the circulation in any other organ. The total blood flow through the human kidneys has been variously estimated at from 500 cc per minute, based on comparative values of blood flow in anesthetized animals determined by use of the stromuhr, up to 1,100 cc per minute determined by the use of the low concentration diodrast clearance test. Except for a relatively small amount of blood that nourishes the renal pelvis and parts of the medulla, all this abundant supply of blood passes through the glomeruli and then through a second system of peritubular capillaries. These peculiarities of the blood supply to the kidneys have important relations to the physiology and pathology of these organs. Any pathologic change that reduces the flow of blood through the glomeruli will decrease glomerular filtration and correspondingly diminish the blood supply to the tubules. This is the chief factor in the atrophy of the tubules in chronic glomerulonephritis and in the advanced stages of hypertension.

From the Department of Pathology, Northwestern University Medical School.

Read before the Section on Pathology and Physiology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

Because of the size of the renal arteries, of the right angles at which they leave the aorta and of the manner in which they break up into the numerous branches in the hilus of the kidney, there is relatively little loss of pressure between the aorta and the glomerular capillaries. The hydrostatic pressure of the blood in these capillaries is higher than that in any other system of capillaries in the body and has been estimated to be about 60 per cent of the pressure in the aorta, or approximately 72 mm. of mercury. The hydrostatic pressure in the glomerular capillaries is maintained at a high level throughout their entire course because of the relatively small size of the efferent arteries through which the blood leaves the glomeruli. The efferent arteries are short and quickly break up into a meshwork of capillaries that surround the tubules from their own glomeruli of origin and anastomose to some extent with capillaries from other efferent arteries. The only exception to this is the efferent arteries that leave glomeruli situated in the deeper zone of the cortex. These vessels pass into the pyramids, where they give rise to systems of capillaries that surround and nourish Henle's loops. The hydrostatic pressure in all these peritubular capillaries is low because of the great size of their total cross section and because they open into veins. There are thus two systems of capillaries in the kidneys—the glomerular and the peritubular—transversed by the same blood but with widely different hydrostatic pressures.

The structural pattern of the kidneys is admirably adapted to the performance of their chief function of eliminating in the urine excess of water and certain mineral substances and the waste products of protein metabolism. The formation of urine begins in the glomeruli, but the process is not complete until the finished product is discharged into the renal conduits or collecting tubules. Glomerular filtration is a passive nonselective process of prodigious proportions, accomplished by energy supplied by the heart through the medium of the systemic blood pressure transmitted to the glomerular capillaries. On an average, in the neighborhood of 100 liters of a watery solution of the crystalloidal substances in the plasma in the same concentration as they existed in the plasma pass through the glomerular filter each twenty-four hours. What would otherwise be a wanton waste of needed materials is prevented by selective absorption by the renal tubules.

It is significant that, because of the peculiar structural pattern of the kidneys, two of the most important factors in renal function are purely mechanical, or physical, in nature, namely the hydrostatic pressure of the blood in the glomerular capillaries and the osmotic pressure of the plasma proteins. The normal exchange of fluids between blood and tissues throughout the body depends on the changed relations between the hydrostatic pressure at the arterial and venous ends of the systemic capillaries and the osmotic pressure of the contained plasma proteins, whereby fluids pass from blood to tissues through the arterial portion and from tissues to blood through the venous ends. However, in the glomerular capillaries the hydrostatic pressure of the blood is constantly higher than the osmotic pressure of the plasma proteins, and the direction of the flow of water and solutes is from blood to capsular space throughout the entire length of these vessels. On the other hand, the blood in the peritubular capillaries differs from that in the glomerular system in two important respects. Because of the loss of water from the blood in its passage through the glomeruli, the

osmotic pressure of the plasma proteins is about 25 per cent higher in the peritubular capillaries than in any other system of capillaries in the body. At the same time the hydrostatic pressure of the blood in these capillaries is lower than the osmotic pressure of the plasma proteins. Hence the direction of flow of fluids in this system is constantly from tissue spaces to blood. This is an important factor in the functioning of the tubular epithelium. For water and solutes withdrawn by tubular reabsorption from the glomerular filtrate in the lumens of the tubules and discharged into the surrounding tissue spaces are quickly drawn into the peritubular capillaries by the increased osmotic pressure of the plasma proteins of the blood in these vessels.

The proximal convoluted tubules receive the glomerular filtrate and reabsorb from it all the sugar and varying amounts of urea, chlorides and other substances according to the needs of the body at the time, together with a sufficient amount of water to hold these substances in solution. This portion of the human nephron excretes such foreign substances as diodrast and phenol-sulfonphthalein, but it does not normally excrete any of the usual waste products of metabolism. These are removed by glomerular filtration only. Tubular excretion is therefore a potential factor in renal function, a sort of phylogenetic residuum, rather than a normal constant activity of the tubular epithelium. In some forms of chronic renal disease it is possible that there may be a reversion to this function as a compensatory mechanism in those tubules whose glomeruli have been destroyed but which have retained their peritubular capillary blood supply. Metallic poisons such as mercury bichloride, are not reabsorbed by the tubular epithelium but are concentrated in the tubular lumens by the absorption of water. This portion of the nephron is thus very vulnerable to this type of poison, and this is the mechanism by which the proximal convoluted tubules are characteristically damaged by any dialysable poison which is not selectively reabsorbed. The high osmotic pressure of the plasma proteins in the peritubular capillaries may be responsible for the rapid diffusion of practically all the glomerular filtrate through the layer of dead, functionless tubular epithelium. This furnishes a reasonable explanation for the oliguria and anuria that are characteristic of poisoning with mercury bichloride.

The total amount of glomerular filtrate produced by the kidneys depends on the quantity and the hydrostatic pressure of the blood passing through the glomeruli and on their total filtration surface. Reduction of any one of these factors will, unless compensated, reduce the total amount of filtrate but not necessarily the total quantity of urine. For competent functioning of the kidneys it is necessary that a sufficient quantity of blood under adequate hydrostatic pressure pass through enough pervious glomeruli to insure the formation of the normal amount of glomerular filtrate. All the pathologic conditions that result in renal insufficiency have in common interference with the blood supply to the glomerular and peritubular capillaries. But even in the presence of severe renal disease the competence of the kidneys may be maintained, at least for a time, by one or more of several possible adaptations. When, as in chronic glomerulonephritis, for example, many glomeruli have been destroyed, an increased flow of blood through a smaller number of pervious glomeruli under an augmented hydrostatic pressure may still maintain the total glomerular filtration at a normal level.

PATHOLOGIC CONDITIONS

The two chief pathologic conditions that threaten the efficiency of the kidneys are (1) arteriolar sclerosis with narrowing of the lumens of the afferent arteries to the glomeruli and (2) primary disease of the glomeruli themselves. The former is the pathologic equivalent of long standing hypertension, the latter is glomerulonephritis.

The pathologic changes leading to hypertension appear to occur in three stages. In the first stage there is apparently a functional vasoconstriction which is not readily demonstrable as a structural change. The kidneys receive both vasoconstrictor and vasodilator fibers from the sympathetic nervous system, but under normal conditions they appear to exercise little control over renal function. Completely denervated kidneys are capable of producing a perfectly normal urine. However, the structural basis for sympathetic influence on renal activity is available and it is reasonable to assume that, like other potential functions such as tubular excretion, it may become active when needed or when the proper stimulus is applied. Smith and his co-workers were able to produce a reduction in renal blood flow, as measured by low concentration diodrast clearance, which they described as "ischemia of the kidneys," by injection of epinephrine and neosynephrin and as a result of "marked apprehension." Goldblatt and others have shown that renal ischemia results in the production of renin which is activated in the blood stream to angiotonin. This appears to be capable of initiating a vicious circle, since the kidneys produce renin as long as they remain ischemic and may remain ischemic as long as they continue to produce renin. It is an interesting speculation, wholly unsupported by any direct observations, that repeated states of "marked apprehension" or other fortuitous vasoconstrictor impulses might initiate the vicious circle, in other words, that a condition which began as a sort of physiologic accident might end in permanent hypertension.

The second and third stages of the arteriolar sclerosis are not infrequent in many organs of the body, but, as pointed out by Moritz and Oldt, it is only in the kidneys that they have any constant association with hypertension. The second stage is characterized by hypertrophy of the muscular coat and hyperplasia of the elastic lamina of the afferent arteries. In the third stage the walls of the arterioles become transformed into hyaline tubes with considerably narrowed lumens. In the first two stages the affected arterioles are still capable of responding to vasomotor impulses, while in the final or hyalinized stage response to such stimuli is no longer possible. This functional change due to the structural alterations in the vessel walls may therefore be a factor (1) in the variable response of hypertensive patients to such depressor substances as sodium thiocyanate and colloidal sulfur and (2) in the unpredictable results of sympathectomy as a mode of treatment of hypertension. Neither method of treatment could be effective in the third stage when the arterioles are reduced to hyaline tubes and have completely lost their power to respond to vasomotor stimuli.

Long continued constriction and thickening of the walls of the afferent arteries to the glomeruli threaten renal sufficiency by their tendency to reduce the flow of blood through the glomeruli. That this is not a mere tendency is indicated by the observations of H. W. Smith and his co-workers. They found, in their hyper-

tensive patients, a constantly subnormal renal plasma flow and an early and progressive loss of tubular function as revealed by reduction of tubular excretory mass (high concentration diodrast clearance, or "diodrast T_m "). But as long as the high blood pressure in the renal arteries is capable of driving enough blood through the narrowed vessels to maintain an adequate filtration pressure in the capillaries of a sufficient number of glomeruli, glomerular filtration will continue in adequate amount. Lowering of blood pressure in hypertensive patients, either spontaneously or by means of thiocyanates or colloidal sulfur, would not necessarily affect renal function during the first two stages of the vascular changes characteristic of hypertension. These vessels are then still capable of responding to vasodilator impulses and by dilating would permit the passage through the glomeruli of a sufficient amount of blood under adequate filtration pressure even at the lower level of systemic blood pressure. This view appears to be theoretically sound. For its confirmation or disproof there is needed information, not now available, on the effect in hypertensive patients of thiocyanate and colloidal sulfur on the afferent and efferent arteries determined by actual observations on microscopic sections or on renal blood flow as determined by the clearance of diodrast at low plasma concentration.

As this disease progresses, more and more arterioles become so reduced in size that, in spite of the hypertension, the glomeruli and tubules which they supply become so ischemic that they are rendered functionally incompetent. This is the probable mechanism by which the constantly subnormal renal plasma flow and the early and progressive loss of tubular function observed in hypertensive patients by Smith was brought about. Such a progressive condition, particularly in persons under 50 years of age, may ultimately lead to complete renal insufficiency and death from uremia, while in older patients, because of the slower progress of the disease, death more commonly follows cardiac decompensation or cerebral hemorrhage.

The anatomic counterpart of clinical hypertension is a relatively simple change in the walls of the renal arterioles, and its potential effects on renal function are reasonably clear. But the correlation of the pathologic changes in the kidneys with disturbances in renal function in glomerulonephritis is far more difficult. Not only are the lesions in the latter disease more complex, but they are also more varied. They range from the simple accumulation of leukocytes in the glomerular capillaries and capsular space through capillary thrombosis and proliferation of endothelium to final complete fibrosis of the entire glomerulus. During the progress of this process the efficiency of the glomeruli as biologic filters is steadily reduced, partly by diminution in the blood flow through the affected vessels and partly through thickening of the walls of the capillaries. In continuously progressive and in repeatedly intermittent glomerulonephritis, sometimes early, sometimes late, reduction and final complete cessation of blood flow through glomeruli reaches such proportions that the factor of safety, or functional reserve, of the kidneys is exceeded. For this reason, when this disease progresses to its natural termination it ends inevitably in renal insufficiency and death from uremia. However, every experienced pathologist has seen functionally normal kidneys in which characteristic scars furnished valid documentary evidence of the existence of previously active glomerulonephritis whose progress had been arrested before renal insufficiency occurred. But, before

the final natural termination of the disease is reached, complications secondary to the changes in the kidneys may arise and cause death.

The primary lesion in glomerulonephritis is generally regarded as a nonsupportive type of inflammation. But this differs from ordinary inflammation in several important respects. In the first place it is not due to the actual presence of bacteria. The source and nature of the irritant or injurious agent are unknown. If the toxic agent is colloidal, that is, nonfiltrable, its selective action on the glomeruli may be explained by its concentration in the glomerular capillaries as a result of loss of water in the process of filtration. Whatever its origin and mode of action, it may initiate processes that are capable of progressing without the continued presence of the injurious agent. The permanent effects often appear to be the results of repair of the damage rather than of the primary injury.

The structural pattern of the glomeruli modifies the inflammatory process. Any exudate that forms will be carried away with the filtrate as long as the glomeruli affected are capable of producing filtrate. This mobile exudate usually disappears before serious permanent damage is done to the glomeruli. In the acute glomerulonephritis of scarlet fever, polymorphonuclear leukocytes may accumulate in considerable numbers in the capillaries of the glomeruli and in the capsular space. Perhaps it is because this type of glomerulonephritis is more definitely exudative than many other forms of the disease that scarlatinal nephritis rarely becomes chronic or proves fatal.

In other types of glomerulonephritis, particularly in the chronic form, the primary lesion in the glomeruli is proliferative in nature. The proliferation may involve either the endothelium or the connective tissue or both. Proliferation of the endothelium lining the glomerular capillaries reduces or completely occludes their lumens, thus inducing ischemia of the affected glomeruli and their accompanying tubules. In the acute and chronic forms of glomerulonephritis characterized by this type of lesion, the glomeruli are large, hypercellular and bloodless.

In both acute and chronic glomerulonephritis, injury to the glomeruli results in an increase in their permeability that permits the escape of serum albumin. As long, therefore, as a damaged glomerulus is capable of producing filtrate the filtrate will contain serum albumin. The loss of serum albumin from the plasma is greatest in lipid nephrosis and in chronic glomerulonephritis with the nephrotic syndrome ("nephritis with edema"), in which it is often difficult to demonstrate any structural change in the glomeruli themselves.

Mild hypertension is often associated with acute glomerulonephritis. This is apparently due to mild renal ischemia, in the production of which two factors operate. In the first place, the flow of blood through the glomeruli is impeded by the proliferation of endothelium, by the accumulation of exudate or by thrombosis in the capillaries, and, second, the swelling of the kidney within its fibrous capsule increases intrarenal pressure, which augments the resistance to the flow of blood through the kidneys. Depending on the intensity of the action of these two factors, alterations in the quantity of urine excreted, from oliguria to complete anuria, and variable degrees of retention of nitrogenous waste products to almost complete renal insufficiency may occur in acute glomerulonephritis.

Chronic glomerulonephritis may be roughly divided into two types: the azotemic, accompanied by nitrogen

retention, and the nephrotic, accompanied by edema. In the azotemic type the changes are proliferative and obstructive in nature and cause earlier and more serious interference with the circulation through the glomerular and peritubular capillaries. The affected glomeruli are ultimately reduced to avascular scars, and the associated tubules atrophy or completely disappear. There are thus a gradual destruction of glomeruli and a progressive reduction in their total filtration surface. Clinically the blood pressure increases; the kidneys lose their power to excrete either a concentrated or a dilute urine, and albuminuria is slight or moderate in degree. Since the afferent arteries are not involved the hypertension increases the filtration pressure in the remaining intact glomeruli, thus producing a greater quantity of filtrate to each glomerulus. This augmented filtrate flows more rapidly through the tubules, and reabsorption is less complete. Furthermore, involvement of the glomeruli in the deeper zone of the cortex diminishes the blood supply to Henle's loops and thus interferes with the function of the tubules that are primarily concerned with the final concentration of the urine that renders it hypertonic to the blood. These two factors—rapid flow of filtrate through the tubules and reduction of the blood supply to Henle's loop—appear to explain the inability of the kidneys in chronic glomerulonephritis to excrete a concentrated urine.

The progressive destruction of glomeruli finally exceeds the factor of safety or functional reserve of the kidneys and then retention of nitrogenous waste products begins. In the final stages, progress may be very rapid and the onset of uremia may occur suddenly without previous clinical warning. On the other hand, in more slowly progressing glomerulonephritis the development of hypertension may proceed more rapidly than the diminution in total filtration surface of the glomeruli, so that some patients with this disease die from congestive failure of a severely hypertrophied heart before the disease has progressed to a stage at which renal insufficiency ends in uremia.

In lipid nephrosis and in the nephrotic type of chronic glomerulonephritis the glomeruli are well filled with blood and the walls of the capillaries for some reason not readily evident, become hyperpermeable. Serum albumin escapes into the urine in large quantities until the osmotic pressure of the plasma proteins is reduced below a critical level at which less fluid reenters the systemic capillaries than leaves them, and typical nephrotic edema results. This loss of albumin may also have other effects. The osmotic pressure of the plasma proteins in the blood of the peritubular capillaries is also reduced, and, on the principle that has been stated, may interfere with the reabsorptive function of the convoluted tubules.

During the nephrotic stage of chronic glomerulonephritis and in lipid nephrosis there is neither hypertension nor retention of nitrogenous waste products, because there is neither ischemia of the kidneys nor interference with glomerular filtration. Later in the course of nephrotic chronic glomerulonephritis the changes in the kidneys assume the characteristics of the azotemic type, and proliferative and destructive changes in the glomeruli cause progressive reduction in the number of functioning renal units. This alteration in the structural pattern of the disease has two significant results: it induces renal ischemia with gradually developing hypertension, and it diminishes the loss of serum albumin. The plasma proteins then rise above the critical edema level and the nephrotic

edema disappears spontaneously. From this stage onward the progress of the disease is similar to that of the azotemic type, with ultimate death from uremia. The hypertension may for a time maintain renal function above the level at which uremia is threatened. But it also causes hypertrophy of the heart that may end in congestive heart failure and cardiac edema. Thus a patient with chronic glomerulonephritis may have edema of two different types during the course of his disease, and in each case the edema is due to a different cause and develops by a different mechanism.

Because of their peculiar structural pattern, the functional activity of the kidneys depends on two purely physical or mechanical factors: the hydrostatic pressure of the blood in the glomerular capillaries and the osmotic pressure of the plasma proteins. The changes in the afferent arteries and in the glomeruli that result in renal insufficiency have in common interference with the blood supply to the two systems of capillaries in the kidneys. As long as a sufficient amount of blood under an adequate filtration pressure passes through a sufficient number of functioning glomeruli, the kidneys will continue to function efficiently. Although the pathologic changes that induce renal insufficiency are known, we are still ignorant of the causes of these changes.

303 East Chicago Avenue

NUTRITIONAL ASPECTS OF FEEDING AN ARMY

PAUL E. HOWE, PH.D.

Colonel, Sanitary Corps, Office of the Surgeon General, U. S. Army,
WASHINGTON, D. C.

The army ration used at present in training areas, i. e. the type A field ration, presupposes that normal food supplies are available. Its basis is a series of menus for a month, with the corresponding quantities of food required to prepare them. The menus planned must be balanced—nutritionally adequate—and cost not more than the value of the garrison ration at the time and place of issue. They must be prepared two months in advance in order that the quartermaster may have sufficient time to purchase the food. Menus may be modified by authorized persons in accordance with the supplies available or because of changes in the cost of the prescribed food at the time of issue. The menus are prepared under the direction of the corps area commander or by such post or station commanders in his corps area as he may designate.

The menus themselves are usually prepared by representatives of the schools for bakers and cooks or by menu boards consisting of representatives of the major organizations that are to use them. In some cases the menus and estimated quantities of food to be served, together with a dietary analysis, prepared by the food and nutrition officer accompany the menus when presented to the commander for approval.

The requirement that menus shall be adequate and pleasing places on the corps area commander a responsibility that requires technical assistance. In this the surgeon, in his role as adviser to the commanding officer with relation to the health of troops, checks the menus and the quantities of food prescribed to determine the acceptability and nutritional adequacy of the ration. In

this work he has the assistance of food and nutrition officers of the Sanitary Corps.

The plan of rationing followed in the Army recognizes that (a) the adequacy of the dietary is the essential consideration, (b) such a dietary may be obtained in many ways, (c) there are differences in the availability of foods in different parts of the country, and (d) within reasonable limits dietary habits should be honored. It follows therefore that the ration as actually eaten in the camps in different sections of the country may vary widely. There may be substitutions of foods in the menu because those prescribed are not available or because kinds or quantities of foods must be modified to adjust to the value of the garrison ration at the time of issue. Changes in nutritive value may occur because of improper storage, overcooking or preparation too long before the food is to be served. Furthermore the choice of foods for a menu and the methods of cooking in the particular mess influence the amount of food actually consumed by the soldier. All these factors introduce problems that require constant attention if the adequacy of the dietary is to be maintained. Officers of the Medical Department contribute to the solution of these problems by anticipating difficulties and making constructive recommendations to correct them.

When troops move into areas where the type A ration cannot be provided, they may receive an initial issue of the type B or nonperishable ration, after that this ration is forwarded to them automatically unless the commanding general requests otherwise. When local supplies are available, they are used in place of corresponding items in the type B ration.

While the majority of the troops are cared for by "rationing in kind," a small proportion of the organizations receive a money allowance corresponding to the value of the garrison ration, with which to purchase their own food. In these cases the responsibility for the character and adequacy of the dietary rests with the organization commander. The adequacy of the dietary of such messes cannot be reviewed with the same care as the field rations, although Medical Department officers do check the operations of these messes. A slight modification in the method of keeping the records of these messes with very little work on the part of the mess sergeant, will make possible a nutritional accounting of such organizations. This will help to assure an adequate dietary and simplify the review on the part of the commanding officer or the surgeon.

The Army considers that food and its preparation are important factors in morale. The present system of rationing in kind lays the groundwork for adequate dietaries. The chief difficulties encountered are those of wise selection with due regard to regional food habits, and the problems of transportation and of preparation to conserve nutrients and provide pleasing meals. Where difficulties of transportation limit variety, good cooking can do much to overcome the effects of a restricted choice of food. Fortunately, the soldier is an adaptable person, he will accept the inevitable and compensate with characteristic comment.

A review of the operations of the Army in the training camps in this country during World War I and the present war indicate that we have made little, if any, change in either the selection of foods or the adequacy of the ration. It is surprising to find that the ration followed then so nearly meets today's standards. The calcium and riboflavin intake tended to be lower in some

camps in World War I, largely because of the composition of the garrison ration. Even in this regard many camps had as much milk as is now used. If there are to be improvements in today's rations, they will come largely through the realization that, while a good ration may be planned and issued, improper preparation, overcooking, and long standing before service may destroy nutritive values and thus nullify an otherwise good diet.

We are in a much better position today to evaluate and plan adequate dietaries for troops sent overseas or on special details where it may be necessary to restrict the variety of food served, to depend largely on foods that are processed, or to conform to the limitations imposed by transportation or by varied climatic conditions. A number of special rations have been devised for troops operating under unusual situations, such as tanks, the tropics, mountains and desert,

TABLE 1—*Classes of Food and the Major Contribution of Certain Nutrients Made by Each Class to the Army Dietary*

Class of Food	Contribution of Nutrients (10 Per Cent or More)
Meat	Calories protein fat phosphorus, iron vitamin A thiamine riboflavin nicotinic acid (niacin)
Eggs	Riboflavin
Dairy products	Protein fat calcium phosphorus riboflavin
Fats edible (butter)	Fat vitamin A
Fats cooking	Fat
Grain products	Calories protein carbohydrate calcium phosphorus iron thiamine nicotinic acid (niacin)
Legumes and nuts	Iron
Sugars	Calories carbohydrate
Leafy green and yellow vegetables	Vitamin A ascorbic acid
Tomatoes	Ascorbic acid
Citrus fruits	Ascorbic acid
Potatoes	Ascorbic acid nicotinic acid (niacin)
Vegetables other	Ascorbic acid
Fruits other	

all designed to meet emergency needs as to adequacy, palatability and stability.

The Army's problems of planning and reviewing dietaries and of advising with regard to nutrition are not fundamentally different from those encountered in institutions or even in private practice. Two factors are involved: (1) meeting the nutritive requirements for the particular situation and (2) selecting foods that are acceptable to the group or the individual and the preparation and service of these foods in a pleasing manner.

Our knowledge of nutritional requirements has advanced to the point where the Food and Nutrition Board of the National Research Council has set up provisional allowances for nutritional requirements, including those for certain of the vitamins. The general nutritional allowances are fairly clear. The vitamin allowances represent standards which are desirable, although under certain conditions they may be difficult to attain. Since this is true, a set of less liberal vitamin allowances is needed for the guidance of physicians and others who are called on to prescribe dietaries or to assess conditions in which food supplies are restricted.

Minimum standards for the vitamin content of foods for which special dietary claims are made have been promulgated under the Food, Drug and Cosmetic Act.

These are much lower than the vitamin allowances considered desirable by the National Research Council, and lower than desirable for a dietary that most people should consume. It is important, therefore, to make clear which of these sets of standards is referred to when vitamin requirements are discussed in public, in advertisements and on labels, or when making recommendations on nutrition.

The adoption of dietary allowances leaves unsolved the problem of attaining them and calls for a review of our knowledge of the kinds and quantities of food which will meet them. Most foods, particularly natural foods, are sources of a number of nutrients, the percentage composition of a food is not a necessary index to the importance of that food in relation to the total food intake. Thus, a food having a low concentration of a particular nutrient may be normally eaten in such quantities that it makes a major contribution to the diet and conversely, food rich in certain nutrients may not be eaten in sufficient quantities to make it a major contribution. The losses which occur in storage, preparation or service may seriously lower the nutritive value of a food. Finally, there is a limit to appetite as well as to the capacity to consume food.

It is not possible to rely on an attractive menu with a wide selection of foods or to specify servings of food to ensure an adequate diet. It is necessary to specify the quantities of each of the foods eaten. Simple dietaries composed of rather large quantities of a few well selected foods may be fully as adequate as those composed of smaller quantities of a larger variety of foods. Moreover, as previously mentioned, the value of well selected dietaries may be lost through improper preparation.

There is considerable information available on the composition of foods, but the necessity to meet quantitative nutritive allowances creates a new set of problems, particularly with regard to the labile and water soluble vitamins such as thiamine, ascorbic acid and carotene, and the inorganic elements. In addition, there is the question of the nutritive value of foods as they are actually eaten, i. e. after having been prepared, cooked and kept warm or served at the table rather than their value when produced or packaged. Some information on this point is available, but more is needed.

The extent to which losses in vitamin values may occur is illustrated by data contained in a recent letter from Dr. Robert S. Harris of the Massachusetts Institute of Technology. Dr. Harris writes:

During this term (winter 1941-1942) I had a student undertake for a thesis a study of what happens to the thiamine and ascorbic acid in vegetables served in our Graduate House. He studied string beans, red cabbage, carrots, cauliflower, peas, potatoes, spinach, squash, yellow turnips and broccoli. He found that the loss of ascorbic acid in cooking was approximately 45 per cent and that after standing on a steam plate it was 75 per cent. The loss of thiamine during cooking was 35 per cent, and the total loss after two hours on the hot plate was 70 per cent of the original thiamine content. These figures represent averages in losses of foods. The variation between different vegetables during cooking extended from a loss of 85 per cent of ascorbic acid for string beans to 95 per cent for red cabbage. The loss of thiamine in cooking extended from 5 per cent for potatoes to 85 per cent for red cabbage. Total loss of thiamine after cooking and standing on the hot plate ranged from 29 per cent for potatoes to 85 per cent for carrots. The total loss of ascorbic acid for these foods after standing on a hot plate varied approximately 25 to 96 per cent.

Some simplification in our evaluation of foods seems indicated by these added complexities created by the vitamins. A useful procedure is to classify foods somewhat arbitrarily, either on the basis of their similar nutritive value or because of the particular contribution they make to the average dietary. We have found the classification given in table 1 useful in evaluating the soldier's ration. Opposite each class is indicated the nutrients contributed in amounts of 10 per cent or more to the total amount of nutrients in the average army dietary.

The distribution, of course, will be somewhat different in diets in which the quantities of food differ. The order, however, is roughly the same. The average consumption of various classes of foods and the detailed contribution of these classes in an average dietary prescribed for the soldier is given in table 2.

The second major problem in attaining adequate nutrition—that of food selection and preparation—is complicated by established food habits, by folkways, by emotional reactions and, to a certain extent, by arbitrary teaching patterns. The problem has also been compli-

be obtained. To this end a prescription of lists of classes of foods such as that set up in the National Nutritional Program should be accompanied by statements to the effect that "this is a good diet", "there are many ways of obtaining an adequate dietary", "it this one does not fit your food habits or pocket book ask for further advice."

The medical profession will be looked to increasingly for advice on nutrition. Physicians must recognize the fact that the use of food groups or classes and menu plans are devices which have had to be reduced to the danger point of oversimplification. Their use may lead to some difficulties. It is the responsibility of physicians and public health officers, just as it is of the Surgeon General of the Army to recognize the limitations of such devices and to be able to interpret them, and to provide safeguards against their misuse. Just as physicians have the problem of modifying the usual treatment for particular cases, so they must be able to supplement or modify the more or less rigid "food lists" or "dietary allowances" to fit the particular conditions for which they are prescribing. Adequate

cated by the use of biased presentations of nutritional facts in the sales promotion of foods and food concentrates offered on the market. Some of the difficulties in getting people to eat foods are related to the methods of preparation rather than to the foods themselves.

The present emergency will call for many adjustments in food habits on the part of the civil population. It will require sound advice from physicians and others to assure the consumption of adequate diets. In attempting to adjust dietary habits to new conditions it is well to make some provision for improving methods of cooking. A sound nutritional program is based on recognition of the fact that, while certain foods are important, no one of them is essential. It recognizes the possibilities of attaining an adequate dietary in a variety of ways. In every instance there are several kinds or classes of foods which can be used interchangeably to supply the nutrients needed. In prescribing a nutritional program for a civilian group, care should be taken not to interfere with established food habits any more than is necessary to correct the nutritional deficiencies. The program should anticipate as far as possible changes in the kinds and characteristics of available foods in order to prevent frustration and dissatisfaction when customary foods can no longer

food plays an important part in maintaining good health and good morale. Both our army and our civilian population are entitled to be well fed, and the means are at hand to provide them with adequate and satisfactory diets with the minimum of deviation from accustomed food habits.

ABSTRACT OF DISCUSSION

DR JOSEPH W MOUNTAIN, Washington, D C. I should like to ask a question. In the previous paper I was struck by the tremendous loss in food value, notably vitamin content brought about by the cooking process. Colonel Howe mentioned the necessity of devising methods of cooking or preparation which would not entail such losses in value. I should like to have him elaborate on those procedures.

DR J D LEAKE, Washington, D C. We know the process in the laboratory in the preparation of bacteriologic mediums. It makes a difference when it is at a lower temperature. What would you say as to pressure temperature versus prolonged cooking at lower temperature?

DR PAUL E HOWE, Washington, D C. Dr Mountain's question is difficult to answer. We have little information on the losses in cooking. There are good methods—well trained dietitians know how to conserve the nutrients. On the other hand, by the time some foods reach our tables they have lost more than they should. As Dr Goodhart showed the losses

may be greater after the cooking is completed than they are during the process of cooking. Furthermore, such factors as the time of cooking and the reaction of the food influence the loss of vitamins. There are simple ways of cooking. We can perhaps learn how to cook and eat food while a little underdone and thus reduce the losses in cooking. There is some evidence that the fat which the southerner likes on string beans may be somewhat of a protection to vitamin C. I don't know how much. In reply to Dr. Leake's question with regard to pressure cooking—in general, pressure cooking is better. Time and temperature are involved. For pressure cooking the temperature is a little higher, but the time is shortened. These factors are probably the major ones in pressure cooking. Pressure cooking is desirable under most circumstances. The German army uses pressure cookers in its messes when they are not in the field.

NUTRITIONAL ASPECTS OF FEEDING IN THE UNITED STATES NAVY

ERNEST W. BROWN, M.D.
Captain M. C. U. S. Navy (Retired)
WASHINGTON, D. C.

In approaching the topic of this paper, may I remind the reader that there is no more important single factor in building and maintaining high morale and keenness in naval personnel than an acceptable diet of high nutritive value. In fact, the import of optimum nutrition, in relation to physical fitness, can hardly be overemphasized. Modern naval warfare presents enormously increased hazards and a continuous state of tension, increased tremendously by the advent of air power, a heavy toll being laid on the physical and nervous stamina of the operating personnel. Not only must the food supply be adequate in quantity, but the variety must satisfy the requirements of a well balanced ration. This poses a difficult problem which can be met only by careful preplanning and skilful supervision.

The administrative responsibility for the subsistence activities of the Navy lies in the Supply Corps, which procures, stores, issues, prepares and arranges for the service of food. This requires a knowledge of raw and processed foods, storage requirements and spoilage factors, information as to the basic facts of nutrition and ability to direct the preparation of acceptable food. The Supply Corps also conducts training schools for subsistence personnel.

It appears pertinent, in this connection, to direct attention to the magnitude of the service of the supply of food and other items required to maintain a two ocean navy. Under the conditions existing two years ago, this force afloat approximated 100,000 men. Let us visualize this force, divided into many units of less than 100 up to 1,500 persons and distributed from, say, Lisbon to the West Indies, along our Pacific Coast, in Alaskan waters, the area of the Hawaiian Islands and in and around stations in the eastern Pacific. Now consider that the vast majority of these units are immobile, seldom remaining for long periods in the same area. Then visualize the requirements of these units in food, clothing, bedding, tools and nearly every known

item of material required in the upkeep, maintenance and repair of several hundred well ordered floating industrial establishments. This involves the complex problem of procuring and supplying approximately 50,000 items of material and having them where they are required by each unit in this two ocean navy. This may give some concept of the complexity of the administration of supply afloat with which the Navy is confronted, enormously magnified by the present major war.

THE NAVY RATION

The term "ration" in the naval service is defined as the allowance of food per man per day. This was laid down by an act of Congress in 1933, which specified the exact allowances of each item, these being presented in table 1. This law accomplished changes in basic allowances in conformity with the newer knowledge of nutrition. It prescribed increases in fruits and vegetables, both fresh and canned, and larger amounts of milk, substantial increases, therefore, being made in the protective foods. At the same time, certain decreases were directed in certain sources of proteins, fats and carbohydrates.

Under the Navy Ration Law, the quantity of food allowed per day per man is fixed, and issues must be accounted for by rations. However, any article comprised in the ration may be issued in excess of the authorized quantity, provided there is an underissue of equivalent money value in some other article or articles. The system is, therefore, highly flexible from the nutritive standpoint, but the accountability is rigid.

This underissue and overissue feature provides most desirable elasticity. For instance, any saving in underissue of the bread, meat, beverage, cereal, lard and oil ration can be utilized as a basis for the overissue of such foods as fresh fruits, fruit juices, fresh vegetables and milk. This flexibility has further advantages in that it is adaptable to virtually all climatic and market variations, the ration being based on issues in kind, the money value applying only to interchanges of allowances thereon.

Although the underissue and overissue principle holds in general, there are a few minor limitations in the allowance of specified items, which should be mentioned at this point. Thus, the fresh vegetable ration must contain a minimum of 40 per cent Irish potatoes. Beef, fish and liver shall not be less than a prescribed fraction of the total meat issue, and pork, poultry, sausages, veal, mutton and lamb shall not exceed certain proportions of the total meat issue—these directives being modified in tropical waters to the end of improved dietary adjustment to climate. However, the main objective of these restrictions is administrative rather than physiological.

There are forty components listed in the Navy ration, and this limitation leads to the question as to the availability of additional articles desired. This may be accomplished by the following procedure. The complete ration entails a definite cost level contingent on market conditions in the particular locality. Congress, however, stipulated such liberal allowances in the Ration Law that certain savings are often possible with economical administration consistent with adequate subsistence. A certain fraction of these savings is authorized for the procurement of miscellaneous items not specified in the official ration, such as oysters, clams and ice cream—this however, being only an occasional practice.

From the Bureau of Medicine and Surgery, Navy Department.
Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1942.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

While the Ration Law administratively operates satisfactorily in the fleet at large, certain difficulties are encountered in subsistence activities in small units. The Secretary of the Navy is, therefore, authorized to increase the food allowance in vessels carrying a crew of less than 150 men when, in his opinion, these craft are operating under conditions which warrant such additions.

Cost—The fact that the Navy ration is a food and not a money allowance renders it adaptable to naval vessels in any port of the world. But this provision does not relieve the commissary officer of economical procurement consistent with satisfactory subsistence. This, in turn, brings up the question as to budgetary limitation of naval rationing in general by Congress. The annual appropriation is based on the average cost of the ration for the entire Navy for the previous fiscal year, justified overexpenditures being met by a deficiency appropriation.

Nutritive Value—Nutrition surveys for the quantitative and qualitative evaluation of nutritive adequacy, on the basis of actual food consumption, have not been conducted in the Navy. It is my opinion that such studies should be considered at this time. Dependence is now placed on experience tables supplemented by an expanded proportion of the protective foods in accordance with modern practice. There has been an increasing awareness of the newer developments in nutrition in the formulation of menus by both commissary and medical officers.

It appears highly probable that the fuel value requirements of personnel are fully satisfied by the Navy ration. In fact, it should be pointed out that calorific demands have been materially reduced in the modern navy as a result of mechanization of many operations. For example, replacement of coal by oil in fueling, thus rendering hand labor virtually obsolete in the adoption of motor craft in place of the boat pulled by the crew, the trend to conversion to mechanization in hoisting boats, loading stores, passing powder, and even in the operation of the steering wheel.

There are a few instances available in which an appraisal of nutritive adequacy has been undertaken from a study of issued rations. Thus, Lieutenant Commander J. R. Phelps,¹ M. C., U. S. Navy, reviewed in 1925 the records of the rations which had been compiled from three battleships, covering a two months period. Assuming a total waste of 20 per cent, he reported the net fuel value as 3,700 calories computed on the basis of standard food composition tables. Again, allowing for 25 per cent loss of protein by waste, he estimated the consumption of this nutrient as 125 Gm a day and concluded, from this rough approximation, that the crews had a sufficiency of food, a rather excessive fuel value and enough variety of proteins to furnish all essential amino acids. He considered, however, that there were indications of a deficiency in protective food components.

Another study of Navy ration nutritive values was conducted in the case of the battleship *Arizona* in 1940, the data being listed in table 2. This was based on a study of the total food issues for a daily average of 1,200 men collected by Commander E. F. Ney, Supply Corps U. S. N.,² for a period of one year. Acknowledg-

ment is made to Colonel Paul E. Howe, Sanitary Corps, U. S. Army, for the calculation of the nutrient values. The results of another study are also included in table 2, based on the provision requirements per thousand men for a thirteen week cruise of the U. S. Pacific Fleet Base Force in 1941. This involved a total of approximately one and one-half million rations. The nutrient values were calculated by Lieutenant J. A.

TABLE 1—*The Navy Ration*

Articles	Ration Allowance
Total Bread Rations	
Biscuit	8 oz
or Bread fresh	12 oz
or Flour	12 oz
Total Meat Rations	
Meat preserved	12 oz
or Meat salt and smoked	14 oz
or Meat fresh ordinary	20 oz
or Meat fresh boneless	14 oz
or Fish fresh	20 oz
or Poultry	20 oz
Total Vegetable Rations	
Vegetables, dried	12 oz
or Vegetables canned	18 oz
or Vegetables fresh	44 oz
or Vegetables juice	6 oz
Total Fruit Rations	
Fruit dried	4 oz
or Fruit canned	10 oz
or Fruit preserved	6 oz
or Fruit fresh	16 oz
or Fruit juice fresh	6 oz
or Fruit juice, concentrated	0.6 oz
or Fruit juice powdered	1 oz
Total Beverage Rations	
Cocoa	2 oz
or Coffee	2 oz
or Tea	1½ oz
Total Milk Rations	
Milk evaporated	4 oz
or Milk fresh	14 pt
or Milk powdered	1 oz
Total Miscellaneous Rations	
Butter	1.6 oz
Cereals, rice, starch foods	1.6 oz
Cheese	½ oz
Eggs	1.2 egg
Lard or lard substitute	1.6 oz
Oils, sauces and vinegar	2½ pt
Sugar	5 oz
Baking powder and soda	As required
Extracts, flavoring	As required
Mustard	As required
Pepper	As required
Pickles	As required
Salt	As required
Syrup	As required
Spices	As required
Yeast	As required

ClaGue, Supply Corps, U. S. Naval Reserve, of the Bureau of Supplies and Accounts of the Navy Department. Also included in table 2 are the findings of a nutrition survey³ based on an examination of the menus of nine army corps areas of the U. S. Army for a period of six months in 1941.

In comparing the data of the three studies in table 2, it must be borne in mind that these represent only food

¹ Phelps, J. R. The Navy Ration from the Viewpoint of Nutritional Science and Practical Administration. U. S. Nav. M. Bull. 24: 381 (April) 1926.

² Report contained in the files of the Bureau of Supplies and Accounts, Navy Department, 1942.

³ Howe, Paul E. Colonel, Sanitary Corps, U. S. Army. Personal communication, July 3, 1942, to the author.

issues as planned, with no correction for losses due to preparation, table waste or spoilage. The average total food was $5\frac{1}{2}$ pounds in the Army study, $6\frac{1}{10}$ pounds, or 11 per cent higher, in the U. S. S. *Arizona* investigation. The amount of protein issued in the corps area study was less than in both the naval instances. The issues of nutrients were generally higher in both the *Arizona* and the Pacific Fleet Base Force as compared

TABLE 2—Daily Issues of Specific Nutrients for Men

	U S S Arizona *	Base Force Pacific Fleet †	Navy Corps Areas U S Army ‡
Total foods lbs	6.1		5.5

Vitamin C, mg	150	190	140

* For a period of one year for 1,200 men.

† Based on provisions issued for 1,000 men for a cruise of thirteen weeks of the U. S. Pacific Fleet Base Force in 1941.

‡ Based on a study of menus for nine Army corps areas for a period of six months in 1941.

with the Army study. Attention, however, is invited to the probability that the spoilage factor is greater under conditions in naval vessels, thus tending to lower the findings given.

There are presented in table 3 the data of the *Arizona* study, to which a correction has been applied by a deduction of 25 per cent on the assumption that this represents the losses in preparation, table waste and spoilage. This is an arbitrary figure and, in all probability, is excessive under the circumstances. It will be noted that the first column of table 3 lists the food allowances as recommended by the Food and Nutrition Board of the National Research Council.⁴ A comparison of the two sets of data indicated that the consumption of nutrients in the *Arizona* survey holds a favorable position in relation to the Food and Nutrition Board standards. However, the comparison is presented with considerable reservation, especially with respect to the data for vitamins. Whether a comparison of these results is valid is questionable for a number of reasons, which for lack of space will not be discussed. It should be noted that the values for vitamins B₁ and C were further corrected for losses in preparation and cooking. Admitting the limitations attached to conclusions regarding such data, the vitamin content of the dietaries for both the *Arizona* and the Pacific Fleet Base Force gives an impression of adequacy.

New Vitamin Sources—Valuable sources of vitamins have been added to the Navy ration in 1942: vegetable and fruit juices, fresh, concentrated and canned, also flour enriched with vitamin B₁, niacin and iron, and enriched yeast. When it is considered that the storage facilities of even the larger types of naval vessels are sufficient to carry fresh fruits and leafy vegetables for only a few weeks, the value of these new sources of vitamins on protracted cruises needs no accent.

Vessels with a Money Allowance for the Ration—The Navy ration is not issued to small types of vessels

such as destroyers, submarines and submarine chasers. These ships are subsisted on the basis of a money allowance per man per day, under the direction of the commanding officer.

The submarine presents a special dietary problem under war conditions. These vessels are assigned to patrols which may extend sixty days or over. The storage capacity for provisions is so limited that the protective foods, in the form of fresh fruits and vegetables, eggs and milk, can be carried for only relatively short periods; the personnel then subsisting chiefly on meat and preserved foods, largely of the canned type. There appears to be no doubt as to the adequacy of the caloric and protein aspects of the ration, but there is some question with respect to the sufficiency of vitamin and mineral constituents. The possibility has not been put to the test of a nutrition survey, but all submarine personnel are now supplied with a vitamin complex as a means of forestalling any potential deficiency in these items.

ADMINISTRATIVE ASPECTS OF SUBSISTENCE ACTIVITIES OF THE SHIP

The commissary officer of the ship is charged with the administration of the mess, under the commanding officer. He is faced with the problem of menu planning, which involves the factors of availability of an adequate variety of foodstuffs, selection of foods fresh or canned, the itinerary of the ship and climatic conditions. He must construct a well balanced diet which can be translated into interesting and attractive food acceptably served. The factor of nutritive value must be correlated with that of acceptability.

Food Inspection—The Navy makes every effort to procure food of high quality for its personnel. Meats are inspected by personnel of the Bureau of Animal Industry, which has successfully guarded this meat supply for many years. Fruits and vegetables are passed

TABLE 3—Calculated Consumption of Nutrients per Man per Day

Man (70 kg)	National Research Council	U S S Arizona *
Calories—moderately active	3,000	3,059
Protein Gm	70	104
Calcium Gm	0.8	0.7
Iron mg	12	20

Vitamin C mg	75	59

* For a period of one year for an average of 1,200 men, calculated on the basis of an assumed loss of 25 per cent in preparation, table waste and spoilage, additional corrections for preparation and cooking losses applied in the case of vitamins B₁ and C.

on by marketing service inspectors of the Department of Agriculture. Naval inspectors and chemists examine dry provisions. These inspections are supplemented by those of the medical officer when fresh provisions are delivered aboard ship and must have the stamp of his approval.

Training of Subsistence Personnel—It may be of interest to point out that the Navy maintains a cooking school at San Diego, Calif., for the training of subsistence personnel in the preparation and cooking of food. This includes special instructions in methods

of preparation and cooking of food to prevent or reduce losses of vitamins and minerals

The Functions of the Medical Officer—These fall under the following divisions (1) inspection of the sanitary conditions of the galleys and mess spaces, (2) the periodic inspection of all food handlers as to physical fitness for handling food, (3) inspection as to the efficient sterilization of mess gear, (4) inspection of the selection, preparation and service of food, (5) examination of the menu with the objective of formulating a well balanced dietary and (6) recommendations for the correction of any deficiencies found. In other words, he is in theory the trained technical observer of mess operations. In practice, however, this actually requires the services of a nutritionist, the medical officer's qualifications being naturally limited in the technical fields of evaluating the nutritive status of diets and of the preparation of food.

CONCLUSIONS

As a result of the foregoing discussion, the following conclusions have been reached

(a) Complete dietary surveys should be conducted in naval vessels with a view to evaluating the nutritive level of the Navy ration, as a basis for control in assuring an adequate dietary

(b) The policy of assigning trained nutritionists to the larger divisions of the forces afloat should be considered, their services to be utilized as consultants in the planning of well balanced dietaries and in methods for the preparation and service of food

ABSTRACT OF DISCUSSION

DR PAUL E HOWE, Washington D C The basis of rationing in the Army and Navy is different, and neither of them is perfect. The two systems, however, accomplish the same end—a well fed armed force. The Army garrison ration is intended primarily as a basis for determining the money that may be spent for food rather than as a list of foods to be eaten. The Navy sets certain quantities of food and adjusts the various components and alternates, as Captain Brown has indicated. The Navy operates on a system of "and or" with regard to ration components and calculates overages and underages in adjusting to the ration. The Army is operating on a monthly menu and quantities of food to prepare the menus. It is both possible and practicable to set up a ration that is nutritionally adequate and which can be used as a basis for checking the adequacy of the ration as it is issued. Such a plan has worked successfully in other places. We should also have on our ships and in the Army, especially where the garrison ration is in use, a nutritional record which would be on a par with a financial record. Such a record is consistent. Money is provided to buy food why not keep the records, through nutritional accounting in such a way as to demonstrate that the money has been correctly and wisely spent? Captain Brown uses the term "balanced." I wish we could get rid of this term. There is such a thing as balance, but it has such a complex, scientific significance that few of us really know its true significance. The calcium and phosphorus ratio and the interrelation of the members of the vitamin B complex are factors of balance. The word "adequate" is a better term. There is one factor in supplying food for the Navy that Captain Brown did not touch on. They carry stores for long periods of time and hence have higher wastage and greater spoilage. They must, to accomplish the same end, prescribe more perishable food per man daily than the Army.

MYOCARDIAL INFARCTION

CLINICAL FEATURES AND PROGNOSIS

H W RATHE, M D

WATERLY, IOWA

The material studied consists of a group of 274 cases of myocardial infarction seen during, or shortly after, what was considered to be the first attack. The diagnosis was confirmed in every instance by one or more electrocardiograms, in a large majority numerous electrocardiograms were taken, and the diagnosis was based on progressive changes in these records. In only a few cases was a single record obtained, but with the clinical picture the diagnosis was quite certain.

These 274 cases have been divided into three groups (table 1). The first or early fatal group consists of 20 per cent (55) of the total number studied, and it is composed of 36 males and 19 females who died within one month of their first clinically recognized myocardial infarction. The second or late fatal group is composed of 49.2 per cent (135) of the total number studied and includes 99 males and 36 females who lived longer than one month after their first clinically recognized myocardial infarction. The third or survival group contains 30.8 per cent (84) of the total number and includes 59 males and 25 females.

This disease is more prevalent in men than in women. Of the 274 patients included in this study, 194 were men and 80 were women. The ratio of men to women was 2.4:1, which is slightly less than the more often quoted figure 3:1.

AGE FACTORS

The average age of the entire group was 59 years (table 2). The average age was 60.7 years in group 1, 59.7 years in group 2 and 57.6 years in group 3. The age of the early fatal group was 3 years older than that of the survival group. This factor has been previously noted,¹ and Cooksey² and Master and Dack³ have emphasized that the younger persons will more nearly resume their normal activity. The average age of the female group was somewhat older than the male. This was particularly true in the early fatal division, in which the average age of the females was 63.4 years and of the males 58 years.

That the patients who died were older than those who survived is borne out by the fact that 74.3 per cent (141) of the fatal group were over 55 years of age at the time of their infarction, whereas only 63 per cent (53) of those who survived had reached this age.

The age distribution of these patients was as follows: 1.46 per cent (4) in the fourth decade, 14 per cent (38) in the fifth, 29 per cent (80) in the sixth, 36 per cent (101) in the seventh and 17.5 per cent (49) in the eighth decade (table 3). The sixth and seventh decades show the greatest frequency rates. Of the 4 patients in the fourth decade only 1 survives, she had her first

occlusion at the age of 36 years, has had two since, and is surviving twelve years after the first infarction. One of the remaining 3 patients in this decade died within a month after his first infarction. Another became progressively worse and died in congestive failure six months after her first infarction. And the last patient had a second attack six months after the first and died suddenly one year later while overexerting.

50 years or over at onset	94%	38 (74.3%)	103	53 (63.1%)

OCCUPATION

At the beginning of this study it was thought possible that coronary artery disease might be found less frequently in people who were outdoors a great deal or who lived in rural areas (table 4). It will be noted by the table on occupation that persons in rural areas are frequently affected, and in all probability occupation in itself bears very little relation to the etiology of the disease.

TABLE 3—Age Distribution by Decades

HISTORY

A family history of hypertension, cerebral vascular disease or cardiovascular disease was found to be present in about three fourths of the total number (table 5). A definite family history of cardiovascular disease was given by 133 patients (48 per cent).

A hypertension was known to have been present in 173 patients (63 per cent) prior to their first myocardial infarction. The criteria used were those of the Ameri-

can Heart Association, namely a systolic pressure of 140 mm of mercury and a diastolic pressure of 90 mm. The duration of the known hypertension varied from one month to twenty years, the average length of time being 7.1 years. Many of the patients who did not give previous histories of hypertension had never had their blood pressure taken. It was not uncommon in these persons to find definite hypertension present after convalescence from the coronary occlusion was well advanced.

From every patient included in this study an antecedent history suggestive of heart disease was obtained either directly or from a relative or friend. As noted in table 5, dyspnea with or without exertion was the most prominent symptom and was admitted in 194 cases (70 per cent). This had been present from two months to ten years, or an average of 2.09 years. Angina of effort was the next most frequent complaint, and 37 per cent (103) of the group suffered from it in varying degrees. It had been present from one month to ten years, or an average of 1.5 years. Unusual

Surgery	6	2.1
Pregnancy	1	0.5
Fractured hip	1	0.5

fatigue for a period of two to six weeks prior to the occlusion was a major complaint in 32 per cent (92). In several instances a physician was consulted for this complaint alone, and later the typical complaints and findings of myocardial infarction developed. In 19.3 per cent (53) epigastric distress or pain not related to exertion or effort was complained of, and it was thought to be due to the heart disease present.

EXCITING FACTORS

The association of possible exciting factors was considered to be present in 20.8 per cent (57) (table 6). I have seen 2 cases not included in this study in which a diagnosis of myocardial injury due to direct trauma was made. Worthy of special mention was a pregnancy case, a tridecigravida aged 43 who had a known hypertension of one month's duration prior to her first myocardial infarction. She was delivered three weeks after the occlusion and had a normal puerperium. Her activity was restricted for two years, after which congestive failure developed. Gradually she became worse and died three years after her first and only clinically recognized myocardial infarction. Hypertension was present during all this time except for a transitory drop in pressure during the postocclusion period. Unusual exertion and unusual excitement are important exciting factors but are found in relatively few cases.

SYMPTOMS

In 37 per cent (103) there was the complaint of a preliminary pain which I considered to be associated with the major episode of the infarction (table 7). This pain was seldom severe, at least not as severe as the pain to follow, and was described by some as a "distress" or "burning." It was always located either in the retrosternal region or in the epigastrium. Its occurrence varied from an hour to a week prior to the infarction but usually was within a few hours. In several instances this preliminary pain was recognized and a rest regimen and sedatives were administered. This did not prevent the major symptoms from developing, but I did feel that the patient was spared some suffering and shock. This symptom should not be confused with angina of effort, which prior to an occlusion may develop with much less effort than previously. This same observation has been made of dyspnea on exertion.

Severe pain was the most frequent major symptom of the infarction, being present in 56 per cent (154).

TABLE 7—Symptoms Associated with the Infarction

	Cases	Per Cent
Preliminary pain	103	37.0
Severe pain	154	56.0
Moderate pain	35	13.0
Paroxysmal dyspnea	67	24.0

Acute pulmonary edema	13	4.7

TABLE 8—Clinical Manifestations

	Total (274)		Group 1 Early Fatal (55)		Group 2 Late Fatal (135)		Group 3 Survival (84)	
	No	%	No	%	No	%	No	%
Heart rate 100 or over (7 days)	96	35.0	42	76.3	39	28.8	15	17.8
Shock	160	58.4	38	69.0	67	49.6	35	65.4
Muffled sounds	200	72.0	45	81.0	97	71.8	38	69.0
Gallop rhythm	82	29.0	28	50.9	47	34.8	7	8.2
Friction rub	25	9.0	9	16.3	10	7.3	6	7.1
Subsequent cardiac enlargement	182	66.4	34	61.8	113	86.1	35	41.6
Subsequent congestive failure	125	45.6	23	41.8	85	62.9	17	20.2

The duration of the pain varied from one to forty-eight hours, and in some patients a recurring residual pain was noted for as long as two weeks. Pain which was considered to be moderate was complained of by 13 per cent (35) of the patients. Paroxysmal dyspnea was the major symptom in 24 per cent (67) and usually was accompanied by pain but was considered to be the more serious complaint. Unusual fatigue and apprehensiveness were pronounced in 22.9 per cent (63), with distribution as follows: in 52.7 per cent (29) of the early fatal group, in 8.3 per cent (7) of the survival group and in 20 per cent (27) of the late fatal group. In some instances either fatigue or apprehensiveness was noted alone, but generally they occurred simultaneously. Acute pulmonary edema in 4.7 per cent (13) and shock in 1.8 per cent (5) were also found to be prominent symptoms. A complete anuria for twenty-four hours was present in one of the latter group.

CLINICAL OBSERVATIONS

When the heart rate was 100 or over during the first week and continued at this rate, it was usually an ominous sign and was observed in 35 per cent (96) of the total group (table 8). There were 76.3 per cent

(42) of the early fatal group showing this sign. In the remaining groups only 24.6 per cent (54) had a persistent heart rate of 100 or over. Master, Dack and Jaffe¹ found this observation to be of definite prognostic importance, as did Conner and Holt¹. However, Rosenbaum and Levine¹ do not attach quite as much significance to it.

TABLE 9—Blood Pressure

	Total (274)		Group 1 Early Fatal (55)		Group 2 Late Fatal (135)		Group 3 Survival (84)	
	No	%	No	%	No	%	No	%
No change	77	24.4	8	14.5	40	29.6	29	34.5

Delayed rise	59	21.5	3	5.4	32	23.7	24	28.5

Shock and muffling of the heart sounds were important findings from a diagnostic standpoint, as they occurred consistently in all groups.

A gallop rhythm was found in 50.9 per cent (28) of the early fatal group, there were 8.2 per cent (7) in the survival group. In the latter classification half of the instances were found when congestive failure developed months or years after the infarction occurred.

A friction rub was heard in only 9 per cent (25) of the cases. It is likely that this sign would have been found more often had the opportunity for more frequent examinations been possible. This finding is quite variable from patient to patient and its appearance may be very transient, as in some instances it can be heard for only a few hours, whereas in others it may be present for several days.

The subsequent development of cardiac enlargement was found to be less frequent in the survival group than in the fatal group and was of importance in the rehabilitation of the patient.

The development of congestive heart failure was encountered most frequently in the late fatal group: 62.9 per cent (85) of the 135 cases. This, however, did not occur until there had been further occlusions or until considerable time had elapsed after the initial occlusion. In the early fatal group this syndrome did develop in 41.8 per cent (23) and was of serious prognostic significance. Congestive heart failure has devel-

TABLE 10—Multiple Occlusions, 96—31.3 per Cent

	Group 1 Early Fatal (55)		Group 2 Late Fatal (135)		Group 3 Survival (84)	
	No	%	No	%	No	%
Two	10	18.1	2	3.5	13	15.4
Three	0		17	12.5	0	
Four	0		3	0.2	1	1.1

oped in 20.2 per cent (17) of the survival group, in only 0.5 per cent (3) was it found early after the occlusion.

The presence of a temperature of 101 F or over for five days or longer is of importance, however, from a statistical point of view it was determined not to be of prognostic significance in this study. In several of the rapidly fatal cases a temperature of 103 to 104 F was reached and maintained for a few days prior to death.

There was no change noted in the blood pressure in 24.4 per cent (77) of the total series (table 9). In the early fatal cases the blood pressure remained constant in 14.5 per cent (8) throughout the acute phase of the disease. In some instances there may have been a drop in pressure prior to observation, but this could not be determined accurately. In the late fatal cases 29.6 per cent (40) showed no change, and of this number 16 had severe paroxysmal dyspnea as their most prominent symptom. Some of these had acute pulmonary edema as an associated symptom. The greatest number was found in the survival group, in which 34.5 per cent (29) had no appreciable change in their blood pressure findings.

The pulse pressure was 20 mm. of mercury or less in 20 per cent (11) of the early fatal classification. There was only 0.7 per cent (1) in the late fatal and none in the survival group.

A sudden fall in the systolic blood pressure was noted in 56.3 per cent (31) of the early fatal, in 28.8 per cent (39) of the late fatal and in 27.3 per cent (23) of the survival cases. A sudden drop in the systolic blood pressure with an early rise was noted in only 7.2 per cent

TABLE 11—Functional Capacity

	Total Group (274)		Group 2 Late Fatal (130)		Group Survival (61)	
	No.	%	No.	%	No.	%
Lived over one year	16	59.4	86	65.7	77	91.6
Activity Normal			12	21.0	20	71.0
Activity Restricted			71	61.5	57	67.0

(4) of the early fatal, in 24.4 per cent (33) of the late fatal and in 26 per cent (22) of the survival group. There was an absence of early rise in the systolic pressure in 65.4 per cent (36) of the early fatal, 9.6 per cent (13) of the late fatal and 4.7 per cent (4) of the survival group. A delay in the fall of the blood pressure for several days to a week occurred in 28 per cent (78), and a delay in the rise of the blood pressure to a near normal level after a sudden drop occurred in 21.5 per cent (59) of the entire series. Neither of these observations was of statistical significance. The drop in systolic blood pressure during the course of acute myocardial infarction is a common occurrence and not prognostically significant. A sudden drop in systolic blood pressure with a failure to rise again to a level of 100 mm. of mercury within five days was a serious sign.

MULTIPLE OCCLUSIONS

There were 31.3 per cent (96) of the 274 patients considered to have had more than one coronary occlusion (table 10). The criteria used for proving this were clinical manifestations corroborated by electrocardiographic changes and laboratory findings, with the exception of a few instances in which the autopsy and the history furnished the necessary proof.

FUNCTIONAL CAPACITY

The functional capacity of those patients who have been able to undergo graduated activity is considered in table 11. Nearly 60 per cent of the total group and 75 per cent of the survival groups lived one year or longer after their first myocardial infarction was diagnosed.

In group 2, 63.7 per cent (86) lived one year or longer, and of this number only 11 per cent (15)

resumed normal activity sometime prior to their death. Seventy-seven, or 91.6 per cent, of the survival group were living a year or more, and of this group 23 per cent (20) have resumed normal activity. About one half of this number have been advised to restrict their activities somewhat but refused to do so. In 67 per cent (57) the activity is restricted both as a therapeutic measure and in some instances because of limited

TABLE 12—Clinical Course of Death

	Group 1 Early Fatal (50)		Group 2 Late Fatal (130)	
	No.	%	No.	%

exercise tolerance. It was always considered best to limit the physical activity of persons who had been doing heavy work or would do heavy labor unless they were urged to avoid severe and prolonged exertion.

CAUSE OF DEATH

An accurate study of the cause of death was not possible because of a lack of postmortem examinations. The mortality rate for the two sexes was about equal as 68.7 per cent (55) of the women and 69.5 per cent (135) of the men had died at the conclusion of this study. A consideration of the clinical diagnosis as to the cause of death is shown in table 12. In group 1, 60 per cent (33) had a progressive downhill course and died within thirty days. Two of these patients came to necropsy and showed evidence of previous myocardial infarction which had not caused them to discontinue their normal occupation but had caused symptoms. Some of the patients in whom death was sudden or a second occlusion was diagnosed may have had a pulmonary infarction which was impossible to recog-

TABLE 13—Electrocardiographic Patterns

	Cases	Group 1 Early Fatal (50)	Group 2 Late Fatal (130)	Group 3 Survival (61)
Important				
Anterior	47	41.8%	21.5%	50.8%
Posterior	97	32.7%	31.1%	44.0%
Indeterminate	47	21.4%	17.7%	13.0%
Unimportant				
Atrioventricular block	14	9.0%	3.7%	4.7%
Bundle branch block	31	14.0%	22.9%	15.4%
Ventricular fibrillation	3	3.0%	17.0%	10.0%
Right axis deviation	13			
Low voltage	19			
Ventricular tachycardia	2			

nize. Congestive heart failure and subsequent coronary occlusion accounted for 83.6 per cent of the fatalities in group 2.

ELECTROCARDIOGRAPHIC PATTERNS

In the entire group of 274 cases, 87 were judged to have had an anterior infarction, 97 a posterior infarction and 47 could not be localized (table 13). In the early fatal cases 41.8 per cent (23) were anterior, 32.7 per cent (18) were posterior and 21.4 per cent (12) were not localized. In the late fatal group 28.1 per cent (38) were anterior, 31.1 per cent (42) were

posterior and 17.7 per cent (24) were of the indeterminate type. In the survival cases 30.9 per cent (26) were anterior, 44 per cent (37) were posterior and 13 per cent (11) not localized. There is, therefore, a definite predominance of the anterior and indeterminate electrocardiographic patterns in the early fatal group. These findings were similar to those of Vander Veer and Brown,⁴ who found the occurrence of anterior and posterior infarction patterns nearly equal but that a significant percentage of the fatal cases were of the anterior variety. Rosenbaum and Levine¹ found that anterior infarction is more common in initial attacks, whereas Willius⁵ and Master and his group⁶ attached little significance to the localization of the infarct in relation to prognosis. Auriculoventricular block was found in 14 cases and was definitely more prominent in the early fatal group. No prognostic significance could be attached to the 52 cases of bundle branch block, to the 35 cases of auricular fibrillation, to the 13 cases of right axis deviation or to the 19 cases of low voltage which occurred sometime during the course of the disease. Ventricular tachycardia was found in 2 cases. In 1 it was present for two days

TABLE 14—Percentage of Prognosis in Myocardial Infarction Based on Group Totals

	Group 1 Early Fatal (33)	Group 2 Late Fatal (13)	Group 3 Survival (84)
Sinus tachycardia of 100 persisted over 5 days	76.3%	24.6%	
Age of patient over 55 years	74.3%		
Systolic blood pressure sudden drop	36.3%	28.8%	27.3%
Fatigue and apprehensiveness	51.7%	20.0%	8.3%
Heart failure developed	41.8%	62.9%	20.2%
Pulse pressure 20 mm or mercury	20.0%	0.7%	0.0%
Anterior or indeterminate infarction	64.2%	45.8%	43.9%
Gallop rhythm	50.9%	27.3%	8.2%

after the first infarction and recurred with the second attack (which was fatal) nine months later. A second patient had this arrhythmia after his first occlusion and died on the third day.

SUMMARY AND CONCLUSIONS

The purpose of this analysis has been to evaluate the various clinical symptoms and signs as they relate to the prognosis in acute myocardial infarction. The factors considered to be of prognostic importance are listed in table 14 according to their statistical value as determined by a certified statistician.

In this study of 274 cases of myocardial infarction, a poor prognosis was indicated when

- 1 A sinus tachycardia of 100 persisted over five days
- 2 The age of the patient was over 55 years
- 3 The systolic blood pressure dropped suddenly and failed to rise again to a level of 100 mm. of mercury within five days
- 4 Unusual fatigue and apprehensiveness were prominent during the early convalescent period
- 5 Congestive heart failure developed
- 6 The pulse pressure was 20 mm. of mercury or less
- 7 The electrocardiogram revealed an anterior infarction or an indeterminate infarction
- 8 There was a gallop rhythm present

A good prognosis was indicated when the aforementioned factors were not predominant. This was espe-

cially true if (1) the patient was under 55 years of age, (2) the heart rate did not reach 100 or if it dropped within two or three days to 90 or less, (3) the blood pressure returned to a near normal level, (4) the heart was not enlarged and (5) there were no signs of cardiac insufficiency. The patient in whom these good prognostic signs predominate should live many years if carefully managed.

ABSTRACT OF DISCUSSION

DR HORACE M. KORN, Iowa City. There can no longer be any doubt that the xanthine preparations are useful in the treatment of coronary occlusion. As soon as possible after the occlusion has occurred, provided the patient is not in shock, $7\frac{1}{2}$ grains (0.5 Gm.) of aminophylline (theophylline with ethylene diamine) should be given intravenously, and this should be repeated about every eight hours for the first few days. Each dose is diluted to 25 cc. with isotonic solution of sodium chloride, and the rate of injection should not exceed 5 cc. a minute. At the same time, and after intravenous medication has been stopped, the drug should be given by mouth in doses of 12 grains (0.8 Gm.) or more a day, depending on the patient's tolerance. It is important to remember that theophylline with sodium acetate is also effective by mouth, and that the cost, when the two are purchased in large quantities, is only about half that of aminophylline. Theobromine with sodium acetate is likewise useful. In fact, in animal experiments which were recently reported this drug was even more efficacious than aminophylline in preventing death after ligation of one of the coronary arteries. Attention has lately been drawn to the possibility that infarction may lead reflexly to coronary vasospasm, and, as the vagus is the efferent path of this reflex, the use of atropine sulfate in an initial dose of $\frac{1}{50}$ grain (1.3 mg.) intravenously, followed by $\frac{1}{150}$ grain (0.4 mg.) by mouth several times a day for a few days, has been advocated. Preliminary experimental work indicates that this lowers the mortality rate considerably and therefore, if atropinization does not prove to accelerate the heart rate to a dangerous degree, it deserves an extended clinical trial. Many clinicians now administer quinidine sulfate more or less routinely after coronary occlusion whether or not ventricular premature beats are present. It seems to me that this is sound practice. If, in spite of all precautions, ventricular tachycardia does develop and there is no time to try quinidine by mouth, it may be given intravenously. Ten grains (0.65 Gm.) will dissolve in about 60 cc. of a 5 per cent solution of dextrose and the total dose may be as much as 20 or 30 grains (1.3 to 2 Gm.), depending on the gravity of the situation.

DR O. P. J. FALK, St. Louis. Relative to treatment of the immediate attack of myocardial infarction, I have found it of value to give $\frac{1}{2}$ to 1 grain (0.03 to 0.065 Gm.) of papaverine hydrochloride intravenously immediately on the appearance of the preliminary pain that the author so accurately described. This drug has been observed to reduce regional vasoconstriction and the tendency to fatal ventricular fibrillation in experimental animals following coronary ligation. Should there fail to ensue sufficient relief following papaverine, I have not hesitated to use morphine intravenously, $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.01 to 0.016 Gm.), diluted with sterile water, given slowly. I feel that the indications for this plan include not only immediate relief from pain and anxiety, in contrast to the distressingly protracted response we have all awaited, following two to three successive hypodermics of morphine. With such treatment not infrequently does one see a patient in pain and anguish for forty-five minutes before relief comes. On the other hand, intravenous medication not only relieves pain and anxiety promptly but probably has a favorable influence on the resultant shock and possibly on the vasoconstrictor reflexes, which are conceded to play an important role in the immediate and perhaps remote outcome of the attack. The use of aminophylline intravenously is at the present time debatable. I have not employed it routinely in the beginning of the attack unless signs of congestive failure appear. In the second week of the attack I do use theophylline with sodium acetate by mouth.

COMPLICATIONS OF ONE STAGE ABDOMINOPERINEAL RESEC- TION OF RECTUM

THOMAS E. JONES, M.D.

CLEVELAND

It is instructive to review the complications in any series of cases of a standard procedure. One may avoid some, recognize some early and by so doing institute therapy which may reduce morbidity or mortality. Until Jan. 1, 1942 my associates and I have had an experience with more than 500 cases of one stage abdominoperineal resections for cancer of the rectum, some of the complications of which I will enumerate. In general they are those attendant on any major pelvic operation, some are more common, while others, which one might presume to be frequent are significant by their absence.

Parotitis is not common (about 5 per cent). It seems to run in cycles, months elapsing between groups of a few cases. Manning¹ at the Cleveland Clinic reviewed a series of cases in which the biophotometer test was made for the level of vitamin A. A low level is reported as a predisposing factor. He was not convinced from his studies of about 75 cases that there was any relationship between vitamin A levels and the development of parotitis. I doubt the efficacy of its preoperative treatment. I have also been through the trial of radium and roentgen therapy and while it is difficult to evaluate, I am not impressed with its merits. The duration of the process or the percentage of cases that eventually went on to suppuration did not seem to be altered with this treatment. There is sufficient proof that many are mild and subside with no treatment except heat. Our policy at the present time is simple treatment, but if the process is progressive there is nothing so effective as early incision and drainage through the capsule of the gland. The number that go on to definite suppuration is exceedingly small.

PULMONARY COMPLICATIONS

Our series of cases would indicate that these are in definite relation to the incidence of infection in wounds postoperatively. In the early group, which comprises 250 cases, there were several deaths attributed to pneumonia. During this interval records show that there was some degree of infection in 28 per cent of the wounds, whereas in the later 263 cases, in which there was an incidence of 1 per cent of infected wounds there was but one death attributed to pneumonia. The only change in technic during this time was the institution of interrupted alloy steel wire sutures in the closure of the abdominal wounds. Offhand one might jump to the conclusion that it is due to sulfonamide therapy, but this is not the case, as will be shown later. The incidence of pulmonary complications which might necessitate this therapy has been greatly reduced by elimination of infection in abdominal wounds.

Atelectasis is very uncommon in our series. We know that the incidence is much smaller in lower abdominal operations than in the upper abdominal group. A review of the last 250 cases shows only 5 cases. At the first appearance of atelectasis intravenous sodium sulfathiazole or sodium sulfadiazine is given immediately, since most sputums will show

pneumococci. Clinically the use of chemotherapy seems to lessen the severity of the reaction to this complication and aids in the prevention of pneumonia in the collapsed area. Tracheal catheterization is helpful in dealing with atelectasis. This has been ably described by Ransome and Haight from Ann Arbor.

Pulmonary embolism takes its toll, but a review of the cases shows a smaller incidence than one would expect in view of the magnitude of the operation and its extensive pelvic dissection. Most of these cases have ended in sudden death ten days after operation where no treatment could be instituted. We have used heparin in a few cases after there had been one attack with recovery, but without any change in the end results. These cases gave no evidence of femoral phlebitis before the onset, so that treatment was not instituted for that condition. We presume that the embolus was dislodged from the pelvic or iliac veins. In connection with this problem it is significant to note that we have not seen a single case of femoral phlebitis with its sequelae in this entire group of cases when offhand one might expect a relatively high incidence. The explanation is not clear. Keller,^{1a} in reporting a large series of Wertheim hysterectomies, had observed that phlebitis occurred much less often when he used a large Mikulicz dam in the pelvis than when he closed the wound. In that case a large Mikulicz dam which we use to fill up the pelvic cavity posteriorly may serve the same purpose. Also it may be that the extensive destruction of the pelvic sympathetic nerves helps to prevent vasospasm in a permanent way similar to the temporary effect which Dr. Ochsner gets from the injection of the lumbar sympathetic ganglions with procaine in cases of femoral phlebitis, in which he has been so successful in reducing the late morbidity as well as mortality.

PERITONITIS

Foremost among the complications years ago, and the chief cause of death, was peritonitis. I observed on many occasions in my earlier cases that peritonitis was always associated with a dirty infected wound, and it was my opinion that peritonitis was always secondary to it. In cases in which there was no gross contamination whatever it was difficult to explain peritonitis. Following this operation the symptoms generally started about the fourth or fifth day and in most cases were not fulminating from the time of operation. This in association with an infected wound which would appear at the time, makes me feel that it is secondary to deep wound infection. The peritoneum can kill off infection more readily than a wound. Many of these infected wounds would disrupt, and the mortality in such cases was high as the result of the coincident intestinal obstruction. Brubaker and Newell,² in an analysis in a series of 366 of our cases with regard to the problem of infection in relation to wound closure, disclosed the significant fact that in the earlier group in which wounds were closed with catgut there was some degree of wound infection in 28 per cent of cases and the mortality varied in years from 9 to 12 per cent, whereas in the cases in which interrupted alloy steel wire sutures were used with simple clip closure to the skin and elimination of stay sutures the incidence of wound infection was 0.85 per cent. In other words, a moderate infection occurred in only 1 of 116 cases in which the wound was closed in this manner. From the stand-

Read before the Section on Surgery, General and Abdominal at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

point of mortality it is equally impressive. The mortality in the last 261 cases has numbered 12, or 4.5 per cent, which included one series of 82 consecutive cases without a death. One must speak from one's own experience. I am convinced that this type of closure is accountable for most of the success. I have never been an advocate of intraperitoneal vaccine and neither has intraperitoneal sulfanilamide been used in any case in this series, so that they can be eliminated as a helpful factor. Sulfanilamide has been used in only a few cases in the posterior wound when there was gross contamination due to fracture of the growth. I do not wish to convey the impression that I am not a supporter of sulfanilamide therapy. I am, definitely, but I do not think that it is a panacea and I cannot go so far as some who actually believe that it can replace meticulous aseptic surgery. The care of the colostomy is important. The older teaching that it should not be opened until three or four days after operation for fear of wound contamination is untenable. As a matter of fact, I think it predisposes to it. In our cases the colostomy is brought out in the midline incision. It is occasionally opened immediately after operation and very frequently in the first twenty-four hours if there is any distention of the loop. All that it is necessary to do is to protect the wound adequately with petrolatum gauze, rubber or oiled silk. It should be unnecessary for me to call attention to the fact that, in doing a colostomy, one should never stitch the bowel to the peritoneum, fascia or skin as is so frequently pictured in the textbooks. It invites infection. Diverticulosis is frequently associated with these cases, and if one had distention of the loop for several days it is quite possible that rupture of a diverticulum in the abdominal wall portion of the colostomy would give a fatal peritonitis. I saw this occur one year postoperatively with recovery on opening the abscess, but convalescence was stormy.

Paralytic ileus is uncommon. When ileus occurs it is generally due to mild peritonitis or plastic exudate due to various causes. At the earliest recognition a Miller Abbot tube is inserted and left down until it is safe to remove it. This procedure undoubtedly has saved many secondary operations for obstruction and many a mortality.

Death from hemorrhage is rare. There was one death in our series. It was due to uncontrollable bleeding from a sacral vein where the lesion was adherent to the presacral fascia. Retraction of the vein into the sacral foramen made pressure packing ineffective. Postoperative hemorrhage during this first twenty-four hours occurred only occasionally. I think it is generally due to oozing from vessels over the prostate or upper part of the vagina and responds to further packing for pressure. It is advisable to place a suture ligature in the coccygeal vessel when incising the fascia, otherwise the ligature may easily be dislodged during the packing. Removal of the posterior pack to find the bleeding point has had to be done on only two occasions. Ligation of the inferior mesenteric and the middle hemorrhoidal arteries in cases of arteriosclerosis generally makes the operation hemorrhage proof. The most annoying bleeding comes from venous oozing over the prostate and upper part of the vagina. This brings up the question of shock. I must confess that this picture is entirely unobserved in this series of cases. I could not attribute one single death to shock unless one wanted to call the one death from hemorrhage as being shock. The use of spinal anesthesia with a routine transfusion during operation in

all cases eliminates it. The only time we do not use spinal anesthesia is when the patient is elderly and has arteriosclerosis and low blood pressure. Prolonged hypotension postoperatively will give rise to cardiopulmonary or renal insufficiency complications.

INFECTION OF THE URINARY TRACT

By far the most distressing complication is that relative to the bladder. The operation, necessitating as it does the wide pelvic dissection, causes many of the sympathetic fibers which have to do with the physiology of micturition to be destroyed. This altered physiology predisposes to infection, which is most annoying. Cystitis in some degree occurs in about 95 per cent of the cases. The infection is limited to the bladder, clinically. Chills and costovertebral tenderness occur only rarely, 1 per cent. Approximately 15 per cent of the patients will void spontaneously, and in this group the symptoms are mild. Formerly we advocated the use of the retention catheter, but for several years we have resorted to intermittent catheterization, believing that it is the lesser of two evils. Furthermore, in the light of our present day knowledge of urinary antiseptics it may be that continuous drainage does not allow sufficient concentration of the drug in the bladder to be effective. The fever incident to the postoperative reaction usually subsides by the fourth day, followed on the fifth or sixth day by fever due to urinary tract infection, with a slow pulse. The temperature and pulse curve the first postoperative week is characteristic. The average duration of the urinary fever is four days after the commencement of chemotherapy, but it is dependent somewhat on persistence of the residual urine.

About 90 per cent of the bladder cultures show *Escherichia coli*, *Streptococcus fecalis* or a combination of the two. *Proteus vulgaris* and *Staphylococcus albus* account for the remaining 10 per cent. Other organisms are rarely seen.

Sulfathiazole $7\frac{1}{2}$ grains (0.5 Gm.) four times a day is preferred for *Escherichia coli* and *Staphylococcus albus*. *Streptococcus fecalis* responds to sulfathiazole, but it is my impression that mandelic acid controls the infection more promptly when it is due to this organism. Either sulfathiazole or sulfanilamide 10 grains (0.65 Gm.) three or four times daily will control *Proteus vulgaris*, but we lean toward the latter. Combinations of *Escherichia coli* and *Streptococcus fecalis* seem to respond better to sulfathiazole than to mandelic acid. Sulfathiazole is used for all urea splitting organisms except *Proteus vulgaris*, where we still prefer sulfanilamide. Sulfathiazole in the small dosage mentioned rarely causes nausea and no other reactions have been noted. The crushed tablets are easily taken and if anorexia is present or the fluids by mouth must be limited, sulfathiazole is better tolerated than mandelic acid in any form.

It is undesirable to repeat a course of sulfathiazole regardless of the smallness of the dose and it is preferable to continue small doses over a longer period than the usual five or six days if a recurrence in the cystitis is feared. We have had 2 cases of severe reaction to a second course, consisting of high fever, dermatitis and conjunctivitis due apparently to an acquired sensitivity to the drug.

About 90 per cent or more of the patients void with a residual urine of 100 cc or less before leaving the hospital.

At the first appearance of fever due to urinary tract infection a catheterized urine specimen is taken for

culture Sulfathiazole is begun immediately and continued or the agent changed, depending on the results of the culture twenty-four hours later. Whichever chemotherapeutic drug is chosen is continued for six days. Occasionally second courses of chemotherapy may be necessary, but generally the active infection subsides promptly, apparently depending on the decrease in the residual urine. Pyuria persists for several weeks after discharge, but a recurrence of cystitis after the patient leaves the hospital, provided the residual urine is 100 cc or less, is rare.

A retention catheter is placed in the bladder before operation and removed after twenty-four hours. The patient is then catheterized every eight hours until he voids spontaneously. The interval between catheterizations then depends on the amount of residual urine. When it drops to 200 cc, catheterization is done once daily until it is 100 cc or less on two occasions, when catheterization is stopped.

Care must be exercised not to allow the bladder to overdistend. Occasionally at the third or fourth day large amounts of urine will be secreted for a period of two to three days. Under such circumstances a retention catheter is inserted until the polyuria subsides and intermittent catheterization again resumed as aforementioned.

A small percentage of patients who have a persistently high residual urine or cannot void at all for prolonged periods constitute a difficult problem. We treat these patients with an indwelling catheter and intermittent bladder irrigations of potassium permanganate. At the same time a course of acetyl-beta-methylcholine chloride (methylol) is given. The treatment is continued for four days at a time. Despite this and other methods the bladder regains its tone at its own rate, and nothing yet tried seems to hurry the process. Therapy, whatever it may be, must prevent overdistention of the bladder and the recurring attacks of cystitis with repeated courses of chemotherapy.

If in men the bladder is not making progress after the patient is out of bed it is well to make a cystoscopic examination to ascertain the presence of obstruction due to prostatic enlargement or median bar. Many will be able to compensate for slight obstruction before operation, which is lost by inability to contract after operation, and occasionally transurethral resection may be necessary. Patients who have any bladder symptoms preoperatively are given a cystoscopic examination before operation, and many times a transurethral resection is done before resection of the rectum to obviate severe bladder symptoms postoperatively. I have never seen permanent damage to the bladder even though catheterization has to be done in some cases for three weeks and was required in 1 case for thirty days.

Epididymitis is rare considering trauma and some drainage from all posterior wounds, which eventually become slightly contaminated. We have seen only three and here there was some history of previous trouble.

Damage to the ureter accidentally occurred in 2 cases. In 1 the ureter was tied and the kidney subsequently removed with recovery. In the other case the ureter was anastomosed over a ureteral catheter. On two occasions the ureter was purposely divided. Both patients recovered, 1 with removal of the kidney and 1 without.

Prolapse of a loop of bowel through the pelvic floor was not seen in a single case, and in the entire series perineal hernia postoperative occurred only once.

Late obstruction occurred but once. It was due to an adhesion kinking the ileum over the pelvic floor.

New growths in the remaining colon occurred three times, all over two years postoperatively, one in the cecum, one in the transverse colon and one in the descending colon.

IMPOTENCY

In many walks of life today sex seems to be taking a very important role. The abdominoperineal resection is no exception. The great majority of these patients, probably 95 per cent, become impotent. Why about 5 per cent (including a man aged 72) should be exempt is difficult to state, since the operation is anatomically the same in all cases. Impotence is probably due to destruction of sympathetic nerve fibers, including the nervi erigentes. Possibly in a few cases they may escape. I know of no way to prevent it if one is to do a radical operation for cancer. Some patients complain at first but the condition is soon forgotten. Most of it is apparently mental. So far there has not been any suicide on account of it. The patients become philosophical and the topic of conversation centers about the proper management of the colostomy.

2020 East Twenty-Third Street

ABSTRACT OF DISCUSSION

DR. FREDERICK A. COLLIER, Ann Arbor, Mich.: Age may well be called a complication in this disease. Mr. Miles, who devised this operation, fixed his limit rather rigidly at 65 years. For many years I followed his teachings and all I had to offer to the older persons was a colostomy. In one will follow these patients one will find that they die a most dreadful death with constant tenesmus and pain, the disease does not kill quickly. I have felt that I was wrong, and in the past several years I have been accepting any one of any age, provided there is not some other complication, heart, kidney, and so on that precludes the operation. Since January 1 I have carried out this operation on 3 people over 80 and they did very well. I agree with Dr. Jones about the importance of the wound. I have just finished an analysis of two hundred and eighty operations of this sort done in our clinic in the last six years and find, as did he, that an infection in the wound is the commonest cause of death. I think Dr. Jones will admit, however, that this technique of his alone may not be entirely accountable for his excellent results. I cannot go along with him on the site of the colostomy. I used his method of the median colostomy in the large wounds for a number of years, and I have a large number of patients with abdominal walls that have a protuberance about the size of a derby hat. I have yet to see true fibrous union between bowel and abdominal wall. I discontinued that and used the stab colostomy on the left side of the median line. In relation to the bladder, I doubt whether the injury to the nerves plays an important part in these difficulties. In the past few months Dr. Eastman, one of my associates, has made cystometric studies of the bladder before and after this operation on 30 patients and has failed to find any evidence of nerve injury in any single instance. After all, the nerves, as far as the musculature of the bladder is concerned, come from the sacral and pudendal reflexes, which are not involved in the plans of this operation. Our management of these difficulties differs from his, but I think we will agree that neither of us has a perfect way of managing them. We use the indwelling catheter, using the tidal irrigation. In the clean urine we use boric acid solution, and in the infected urine we use a weak solution of acetic acid. This is left for a week. Usually the patients will void after this time in a satisfactory manner. Frequently, however, they do not, and it is our habit, then, at the end of three weeks, when they should be going home, to examine the prostate and bladder with a cystoscope, and one finds not infrequently that their difficulties are those of prostatism which has just been tipped over by the trauma of the operation, and we are prepared to do a resection at that time, and we do it.

DR E PARKER HAYDEN, Boston I am struck by the similarity in general between the Cleveland Clinic experience and ours at the Massachusetts General Hospital. No case of peritonitis has occurred in my series of about one hundred and fifty resections of the rectum for cancer. This is undoubtedly pure chance. I am in accord with Dr Jones that incision of the capsule is seldom necessary and that irradiation is of questionable value. Our x-ray men feel that it must be instituted early to shorten the duration of the complication. Atelectasis has occurred at intervals in our experience and has usually yielded readily to change of position and forced respiration. In an occasional case, aspiration of the bronchi has given prompt relief. Thrombosis of upper femorals or iliacs has occurred twice in my own experience, in 1 case with repeated and finally fatal emboli within four days of operation, in the other with recovery and a persistent leg enlargement. I do not have personal knowledge of an instance following abdominoperineal resection in our hospital. The likelihood of peritonitis should be slight, because no anastomosis is left within the abdomen. When an abscess is encountered between the bladder and the rectum or a friable tumor is occasionally ruptured during perineal extraction, the free posterior drainage usually prevents peritonitis. Fulminating retroperitoneal infection is more likely and more serious. I am sure that 5 Gm of sulfanilamide in the posterior wound, combined with oral or intravenous therapy if necessary, is worth while. Dr Jones's figures with regard to the probable effect of the use of alloy steel wire are convincing, and we should all profit by his experience. The value of early opening of a colostomy at the first sign of distention is unquestioned. The Miller-Abbott tube has practically eliminated the necessity of catheter ileostomy to relieve mechanical small bowel obstruction when it occurs. Urinary and sexual difficulties are certainly the complication which one sees so commonly and which are peculiarly a product of this operation, for the reasons Dr Jones has mentioned. Dr Wyland Leadbetter, urologist at the Massachusetts General and Palmer Memorial hospitals, in a study of one hundred and seventy resections of the rectum by different surgeons found serious urinary complications in twenty. Median bar enlargement, with sagging bladder, necessitated transurethral resection in 11 cases, with relief. We have used constant drainage for eight to ten days after operation in most of our cases.

DR GARNET W AULT, Washington, D C It is obvious that something new has been added to the chapter on abdominoperineal resection. I don't believe we know of anybody more qualified than the men we have heard present the complications. They have all presented the early complications. It would be of interest to know what are some of the late complications of this disease. One of the most obvious late complications is intestinal obstruction, small bowel obstruction, from adhesions, from volvulus, from twisting or other mechanical defect within the abdomen. Another thing that must come to attention and has been mentioned is volvulus or obstruction around the colonic stoma. This can present itself as an early or late complication. I have seen 2 patients who had this as a late complication. All are patients having a midline colostomy. Those who do a left inguinal colostomy have ample opportunity to close the left colonic gutter. However, in doing a midline colostomy there is not always opportunity to close the left colonic gutter. These patients have a natural internal aperture for hernia. Our method of identifying this is nothing new. It just makes use of the fact that one has a method of examining within the abdomen by inserting the finger in the colostomy, and if one can palpate the strangulated mass it is of some help in the operative procedure. One loop of bowel was gangrenous and was resected following failure of the Miller-Abbott tube. I do not know what the men in Washington do with their colostomies, but we have had two of these accidents. We do not advocate a hard rubber tip. We advocate the ordinary size 28 F catheter. Another patient gave himself an enema into the mesentery of his sigmoid. Dr Hayden remarked on the angulation and falling back of the bladder. It does occur. One man was unable to void standing up or sitting down, and it was necessary for him to lean forward and temporarily correct the angulation before urination could occur.

AN ANALYSIS OF THE TRENDS IN CANCER RESEARCH

JAMES B MURPHY, MD

NEW YORK

It is not surprising that there should exist a degree of skepticism as to the value of experimental cancer research, for it is true that so far no answer has been found to the broad problem of the concrete cause and cure of the disease. Yet during the last four decades an impressive number of definite fundamental facts regarding the nature of malignancy has been established. It has perhaps been difficult for any one outside the field to get a comprehensive picture of the meaning of the progress. Until recently the experimental studies have been developed along three main lines more or less independently of one another. It is now evident that the cancer problem is so complex that no one approach is likely to give the complete answer. With the rapid accumulation of new knowledge it has become progressively more important to attempt the correlation of each advance so that its significance may be appraised in relation to already established knowledge of the subject.

It is my conviction that the mass of knowledge already accumulated from experimental studies demands formulation, and that such formulations, if made periodically, should be of value in giving meaning and direction to further development of the experimental approach. Some three years ago a committee appointed by the Surgeon General of the Public Health Service made an attempt at a "formulation and clarification" on the basis of some of the more fundamental data available on the subject. For the present discussion a selection has been made of a few of the more important contributions which served as a basis for the conclusions arrived at in the report of this committee.

TRANSPLANTATION

The experimental approach to the cancer problem had its beginning at the turn of the century with the discovery that cancer was prevalent in animals and that it could be experimentally transmitted. During the first decade, in spite of bitter polemics over points which later proved to be unimportant and of time wasted on false leads, a sound foundation was laid for the subsequent development of the field. The studies of the period were centered around the transplanted tumor and yielded some fundamental information on the biology of the cancer cell. As this represents the first experimental approach to the problem, the significance of a few of these observations will be discussed in the light of our present day conceptions.

The fact that tumors can be transplanted in series demonstrates that malignancy is centered in the cells, since the new tumors which result from inoculation are formed entirely by the multiplication of the introduced cells. Thus, removed from the environment in which the state has developed, the malignant property of the cells continues its course through years of transplantation, during which time the tumor is supported by hundreds of different hosts. The cytologic characteristics survive long periods in tissue culture, a condition under which the cells have been removed from influences which might be exerted from other tissues.

Even today, many of the first tumors are still carried and still exhibit not only their malignant property but also the particular individual character of the original tumor from which the transplants were started. Of first importance is the evidence that the intimate contact between the host's tissues and that of the tumor, for which it supplies blood vessels and supporting stroma, does not lead to a cancerization of the host cells. In fact, no evidence has been found in mammals of infective agents capable of transferring the malignant character from one cell to another, nor is there evidence that such agents are associated with the continued maintenance of the character.

Transplantation was found to be limited by the same general biologic laws as those governing normal tissue grafting. Conditions which interfere with or aid the take of cancer grafts are operative in determining the fate of normal tissue grafts. Very early it was recognized that success in transplantation depended on the strain or race of animal used, but the full significance of this was not evident until much later. Now it is known that the absence of genetic differences between the cells of the implants and the host is the determining factor. Tumors arising in a pure line inbred strain are transplantable to all animals of that strain and occasionally show such a high degree of specificity that they are maintainable only within animals of that strain. But tumors differ in the degree to which they retain the genetic characteristics of the animal in which they arise. Some, which have shown a high specificity in early transplants, have been observed to lose some of the specificity. This change appears suddenly and, in the most carefully studied instance, was accompanied by an increased growth rate. Indeed such changes may occur more than once in a given tumor and are considered to represent somatic mutation. If the assumption is correct, and cancer may gain an augmented malignancy through mutation one is tempted to suggest that the original change from a normal cell may be the result of a similar mutation.

The study of factors influencing transplantability of tumors occupied a prominent place in the early period of cancer research with a resulting extensive literature on the so-called natural, acquired and induced resistance to inoculated cells. It was expected that these investigations would throw light on the body's mechanism for resisting the disease and that the understanding of this would lead to improved methods of treatment, this expectation has not been realized. It has already been indicated that what was called natural resistance is not resistance against cancer as a disease but against the introduced cells of another individual of a different genetic make-up. The method used to induce resistance to transplanted tumors has no effect whatever on the origin or development of spontaneous tumors. Genetic differences between hosts, the tissues used for immunization and the tumor cells appear to be the determining factors, and here again the resistance is against the introduced cells and not against the disease. Today this whole chapter is considered largely of academic interest, and the information collected is principally of value as a study in tissue grafting and has resulted in little direct information on malignancy. The only justification for bringing this subject into the discussion is to illustrate the limitations of the transplanted tumor as material for investigation. However, these limitations may not be so definite when animals of a high degree of genetic homogeneity are inoculated with tumors which have arisen in the strain. Here the tumors are approximate

autografts and natural resistance does not exist, nor can resistance be induced by tissue inoculation.

While much of importance as to what may be termed the biology of the malignant cell has come from the study of transplantable tumors, yet "it has not been possible to establish the existence of a strictly specific characteristic of a cancer cell either morphological, immunological, chemical or physical, other than a loss of subordination to the rhythm of division" (Lacassagne). Many claims contrary to this statement have been based on experiments lacking proper controls, a failing not uncommon in this field. It is just this difficulty of finding proper controls which is responsible for many of the controversial claims with which the subject abounds. For a comparison of characters of normal and malignant cells, it is not only necessary to have actively growing tissue, but the tissue should be of the same type as that from which the cancer arose.

GENETIC FACTORS

The investigation of hereditary and predisposing factors in cancer was the second important line to develop in this field. The beginning was a simple test made by several investigators in which it was noted that the cancer rate was higher in the descendants of a cancer mouse than in a general mouse population. On the basis of this observation systematic investigations of the part played by genetic factors were undertaken. Much was expected from the use of the "pure line technique", that is the use of strains so intensively inbred that a high degree of genetic homogeneity was reached. The problem has proved to be far from simple, for it has become evident that a strictly genetic inheritance plays a variable role being the primary factor in some types of cancer and only of secondary importance in other types. In this field there are many controversial points, and ideas are being constantly modified by new findings. Nevertheless an impressive amount of positive information has been accumulated.

One of the most important facts to be established is that the inherited tendency or predisposition to develop cancer is not a general character but is confined in the strains of animals studied to a definite organ or tissue type. Thus one family may have the tendency for lung tumors, another mammary cancer, and a third leukemia. There is some evidence that this predisposition for special types of cancer holds also for man. The most suggestive data come from the observations on tumors in identical twins. In over 50 per cent of instances when cancer occurs in such individuals it has affected both twins, has developed at about the same time, has been in the same organ of the same histologic type, and in some cases the tumors have occurred in the same location of the same organ. More extensive data of this type would be of great value. If the results of animal studies are generally applicable one could not expect to find evidence of predisposing factors in man until the data are analyzed on the basis of tissue and organ specificity. A small beginning has been made in this direction by Macklin who has shown that, while the cancer rate for any given large family may not be significantly higher than the general rate for the community yet in a number of such families which she has studied the occurrence of a specific type is many times higher than the rate for that type in the community as a whole.

The last few years have shown the fallacy of attempts at generalization and the futility of the controversies over the number of mendelian factors involved in the

inherited tendency for cancer in mice. Only one clear-cut example of what appears to be a strong genetic inheritance has so far been established. The tendency for primary cancer of the lung investigated in highly inbred strains of mice, tested by the accepted methods, gives every evidence of being hereditary and represents a dominant character, although the dominance is incomplete. Certain of the data suggest that a single mendelian dominant and possibly modifying genes are involved. The interpretation is complicated by what appears to be a dilution phenomenon, so that the strength of the inherited factor is estimated by the number of foci rather than by the simple absence or presence of tumor. Apparently these different degrees of predisposition to lung tumor are inherited.

The tendency toward cancer of the breast in mice was found to be transmitted in greater intensity by the female than by the male, so this condition could not be due solely to genetic influence. The results of foster nursing have given evidence of the presence of a factor in the milk which definitely modifies or augments the inherited tendency for breast cancer. Briefly, these findings are that mice from a high cancer strain, fostered by a female from a low strain, have a definitely lower breast cancer rate than litter mates nursed by their own mothers. The reverse conditions, namely young from a low cancer strain fostered by females from a high strain, result in a higher mammary cancer rate in the fostered animals than in the controls. The nature of this milk influence is as yet undetermined, nor are there sufficient data at present to justify an evaluation of the relative importance of this in relation to genetic factors or other possible extrachromosomal factors. So far the effectiveness of the milk influence has been established only for mammary cancer, but leukemia tendency, like breast cancer, shows some indication of being transmitted more strongly by females than by males. In any deductions drawn from these results, consideration should be given to the possibility that the cancer tendency may be secondary to or dependent on some other inherited condition. This possibility is suggested by observations on a strain of rabbits with an inherited tendency to develop an endocrine unbalance. Resultant abnormalities in development and function of the mammary gland frequently progress into a malignant condition. Furthermore, the fact that cancer of the breast may be induced by excessive doses of estrogenic substance suggests the possibility that the endocrines may play a role in the general picture.

It is evident from the foregoing account that the importance of genetic factors is variable. The tendency to develop some types of malignancy is definitely inherited, in one type the inherited tendency is somewhat modified by undetermined conditions, while with breast cancer the milk influence seems to be more dominant in determining the tumor incidence than the genetic constitution. Regardless of the nature of the inherited and predisposing factors, the manifestations are the same, these appear to be an unstable or poorly balanced cell system, confined for the most part to an organ or tissue type. There is evidence that some factor or condition is required to bring out the malignant potentiality.

CARCINOGENIC AGENTS

The third important field of investigation to be developed, and one which is occupying the attention of a large group of workers, is the experimental induction of tumors by so-called carcinogenic agents. The report on chimney sweeps' cancer published in 1775 by Per-

cival Potts was the first recorded account of cancer associated with chronic inflammation. By the beginning of the present century a number of physical, chemical and infectious agents causing certain types of chronic irritation were known to be associated with the onset of the disease. In the early reports from the Imperial Cancer Research Fund, Bashford noted "the association of cancer with peculiar and very different forms of irritation." He commented "that, as data increase from year to year, the mediate relation between irritants and cancer in particular sites of the body becomes more and more significant." Yet the leads so evident from this information received no attention from the group of experimental investigators until some years later. It remained for Fibiger to show a possible association between an induced nematode infection and cancer of the rat's stomach, and for two Japanese investigators to induce cancer in rabbits by the application of coal tar. This study of the chemical carcinogenic agents has developed rapidly into the most active field of cancer research. By 1937 a review of the subject contained over four hundred references.

The search for the particular component of coal tar responsible for the cancer producing property led to the discovery of the numerous carcinogenic hydrocarbons: first dibenzanthracene, then benzo(a)pyrene and then methylcholanthrene. The latter, methylcholanthrene is of special interest because it can be derived chemically from bile salts and because of its structural similarity to sex hormones, vitamin D and other naturally occurring physiologically active compounds. Extensive attempts have been made to find a particular grouping of radicals common to all the components which would be responsible for their cancer producing property, but it was soon found that this property was shared by compounds unrelated to the hydrocarbons and even by simple chemicals. When it is considered that X-rays, radium, ultraviolet light, infectious agents and larger parasites all may produce chronic lesions which have the same tendency to become malignant it is evident that the carcinogenic agents have nothing in common among themselves except the effect they produce in the tissues. The mechanism by which the tissue changes are induced by these various agents has not yet been clarified.

There is still no understanding of the mode of action of the carcinogenic agents. Some of the earlier workers, impressed by the systemic effects following local applications, suggested that the activity of the agents depended on the possession of two properties: (1) the induction of local tissue disturbance and (2) the general interference with the body's mechanism for controlling such a disturbance. Recent investigations have led to the conviction that this conception is erroneous. Simple chronic irritation as the principal factor may be ruled out, and there is no evidence that the agents possess the property of direct stimulation of growth. As a matter of fact, many if not all of the carcinogens tend to inhibit growth of cells, even cancer cells. Comparatively small amounts of the chemical agents will cause permanent stunting of young animals, and local application will retard the development of large regions of an embryo. This property may be a clue to the mode of action. The production of a certain amount of tissue damage with a suppression of regenerative processes could represent just the unfavorable condition under which cells might mutate with the development of a new growth property. The expectation that present methods for producing tumors at will, it would be just

[Faint, mostly illegible text on the left side of the page, appearing as horizontal lines of varying density.]

justify in the light of our experience (figs 3, 4 and 5). In the middle third alignment is most important, apposition less so. "Bayonet" apposition is satisfactory. Shortening is not desirable but is not of permanent consequence. Even a small amount of angulation will result in cases of prolonged healing and, in older children, permanent limitation of pronation and supination. In a young child this limitation of rotation causes very little inconvenience but is none the less a deformity.

Since the day of Hippocrates there has been and still is an active discussion of the degree of supination in which forearm fractures should be immobilized. Hippocrates⁶ warned against supination and advocated midposition or slight pronation, while Pare⁷ urged midposition. At first no differentiation was made as to level. Most of the early writers, including Malgaigne,⁸ Volkmann,⁹ Destot,¹⁰ Helferich,¹¹ Lonsdale¹² and Ashhurst,¹³ advocated supination even for fractures of the distal end. Their choice of position was influenced in

cast
tion

sible to follow the stages leading up to malignancy has not been fully realized. Little more can be said than that, in the midst of chronically deranged tissues, areas are found in which the cells have assumed the malignant character.

That new properties of cells may develop under the influence of carcinogens has been illustrated by some very recent experiments. It is true that these studies deal with a highly specialized type of agent, but it still may represent a lead for investigation by others. The production of liver cancer by the azo dye butter yellow in animals on a deficient diet and the prevention of the carcinogenic effect by additions to the diet offers a chance to establish the mechanism in at least one instance. This work is too recent to be conclusive yet, but there is evidence that a breakdown product of the dye affects certain enzyme systems of the liver cells and that cancer cells resulting from this action show a certain amount of immunity to the toxin. This study offers promise for further elucidation of the mechanism through which the agents may act.

ORGANIZATION OF EXPERIMENTS

In the more modern development of cancer research, investigators are showing greater care in the organization of experiments, the elimination of variables and more interest in obtaining information on normal cell processes. As factors in experimental results, whether in transplantation or induction of tumors the importance of genetic constitution and predisposition has become more and more evident. Strains of animals inbred to a point where there is a high degree of genetic homogeneity are now considered almost essential for important experiments. In selecting strains for any given test it is equally essential to have full information as to hereditary and predisposing factors for the various types of malignancy possessed by the animals utilized. Reference has already been made to the fact that much of the confusion with regard to "resistance" to transplanted cancer was clarified by the use of pure line animals. Furthermore it has been established that the degree of predisposition for several types of malignancy may be determined by the use of carcinogenic agents. Thus, in selected strains, mice with an inherited tendency for lung cancer if exposed to the action of coal tar will develop lung cancer at a much earlier age and to a higher percentage of the animals than would normally occur. Mice without the predisposition, exposed to the same agent, will show only an occasional lung tumor. Hybrids of various types involving high and low tumor strains may have an intermediate lung tumor rate, and this lessened predisposition is evidenced by the lower response to the carcinogenic agent. In fact, the degree of the inherited potentiality for lung tumor may be accurately gaged by this method and is reflected not only by the number of animals which develop lung tumors but also by the number of foci in the individual lungs. The same conditions seem to hold for leukemia and mammary cancer. The former may be induced by carcinogenic agents, but only in strains having a predisposition for the disease, and the induction of mammary tumors by estrogens is most successful in strains with a high natural tendency for mammary cancer.

Studies of the kind just referred to may be considered as attempts to evaluate the relative importance of hereditary and predisposing factors on one side and inciting factors on the other side. There is little doubt that

cancer is far more readily induced in strains with definite predispositions. The fact that it is difficult or even impossible to induce tumors in species which rarely or never develop malignant tumors spontaneously, such as pigeons and guinea pigs, suggests that the response to a cancer inciting agent is definitely determined by factors inherent in the strain or species.

VIRUSES

There is insufficient indication at present that viruses play any important role in the general picture, therefore no attempt will be made to discuss at length the possible relation of this group of agents to cancer. The only evidence of importance in this field is derived from the study of a group of fowl tumors which may be transmitted by filtrable agents. As no mammalian malignant tumor has yet been transmitted except by living tumor cells, the relationship of the fowl tumors to mammalian tumors cannot be considered as established. Furthermore there is no agreement as to the nature of the transmitting agents and their relationship to the viruses. In rabbits cancer may develop in virus induced papillomas but here the stages of the process so closely resemble the conditions accompanying the induction of tumor with chemical carcinogenic agents that we are inclined to consider that the virus has no closer association with the eventual cancer than have the chemical agents. In the absence of evidence that the virus is necessary for the continuation of the malignant state and that cancers can be transmitted by the virus, it should be considered merely as having started a process which tends to go into malignancy. Like the chemical and physical carcinogenic agents it is probably not further concerned with the process.

CAUSE OF CANCER

In a general consideration of the cancer problem and the interpretation of the new experimental findings, it became evident some years ago that it was necessary to define what was meant by the term "cause of cancer." Ewing clarified this by pointing out that there were two questions involved: what he termed the causal genesis of tumors has to do with the inciting factors leading up to the development of the malignant state. The formal genesis has to do with the factors responsible for the nature of the cancer cell and its unlimited capacity for growth. A host of agents chemical, physical and biologic known as carcinogens are involved in the causal genesis of cancer, but they may be considered as only starting a series of tissue events or conditions tending to progress into malignancy. Once the malignant state is initiated, these agents have no part in maintaining it.

Considerable information has been accumulated on the causal genesis of cancer, both as to the variety of agents involved and as to the mode of action of some of them. It is through the more complete understanding of this phase that preventive measures may be expected to develop. It is probable that substantial advancement in the methods of treatment will come only with a fuller knowledge of the formal genesis or the mechanism by which the growth capacity of the cancer is maintained. Unfortunately, this important part of the cancer problem is still little understood. If some substantial specific characteristics of the cancer cell could be established, it would serve as an opening lead, but no such character, other than the capacity for growth, has yet been found. The solution here may depend on a further

understanding of the factors which control normal growth and differentiation of cells. Much may be hoped for with the development of newer methods in the intensive work which is in progress along these lines. One such method, the mechanical separation of the various cell components without disruption of their complex units, is yielding valuable new information. Mitochondria, several different types of secretory granules, the minute particles making up the "fundamental ground substance" and the chromatin material may all be secured in relatively pure form and in sufficient amounts for quantitative and qualitative studies. Thus a new basis for comparison of normal and cancer cells is being established. Another investigation which may yield fundamental information on the mechanism involved is based on the observation that certain carcinogenic agents have a selective toxic action on one of the enzyme systems of the cell and that the cancer cells which develop as the result of exposure to this agent have an immunity to the toxic effect. These may seem feeble beginnings to the understanding of the formal genesis of cancer, but the approach to this, the core of the problem, has been particularly difficult. It is to be hoped that those interested in cell physiology, growth and differentiation of tissues may be challenged by the fundamental nature of this phase of the cancer problem.

CONCLUSIONS

The material for the discussion was selected with the idea of showing that sufficient knowledge has already been accumulated to justify the attempt to deduce certain concrete truths and to formulate certain phases of the cancer problem. It is considered that the experimental results which have been reviewed offer definite support for the following conclusions:

- 1 Malignancy is a universal cell potentiality in that any cell has inherent in its makeup the potentiality for unlimited or uncontrolled growth.

- 2 The degree of this potentiality for malignancy is a variable quantity for each tissue or cell type, and this degree is determined largely, if not entirely, by hereditary or predisposing factors.

- 3 The malignancy potentiality of a cell may be developed in the more sensitive groups by the strain of normal physiologic processes but may be set off even in resistant groups by a variety of inciting agents.

- 4 The change from a normal to a malignant cell represents an alteration in the cell itself, by virtue of which proliferation becomes an automatic process independent of a continuously acting provocative agent.

- 5 The new property of the cell appears to develop suddenly, and this becomes a fixed character which is transmitted to all its descendants. It may possibly be the result of a somatic mutation.

At the present time there is no theory as to the nature of cancer sufficiently comprehensive to be taken seriously. In fact, the investigator has come to adopt the attitude that, in this field, a theory not susceptible of experimental examination is not worth discussing. Attempts in the direction of theory building are not advocated now, for there is insufficient knowledge to justify this. But it is believed that much is to be gained by more serious attempts to sort out existing knowledge with the expectation that some sound deductions may be made, which in time will form units from which may be built up a comprehensive formulation of the fundamental cancer problem.

FRACTURES OF THE FOREARM IN CHILDREN

WALTER P. BLOUNT, M.D.

ARTHUR A. SCHAEFER, M.D.

AND

J. HOWARD JOHNSON, M.D.

MILWAUKEE

"Fractures in children are different" and forearm fractures offer many examples in proof of this theme. They must not be considered along with fractures of adults under anatomic classifications which take no account of the growth factor. They are different as to pathologic conditions, treatment and prognosis. Intelligent management must recognize this fact.

Fig 1 (case 1)—Anteroposterior views of both forearms at 15 years of age, nine years after removal of the radial head for displaced fracture of the radial neck. Note the short, small radius with radial deviation of the hand and increased carrying angle. These anatomic conditions are associated with weakness and some discomfort.

The common forearm fracture in the adult is that described by Colles¹ with impaction of the lower end of the radius and with a fracture of the tip only of the ulnar styloid. In children, on the other hand, the commonest fracture is one of both bones at a higher level, 1 or 2 inches above the wrist joint. Greenstick fractures are common in children and rarely occur in adults. Perhaps the best example of the differences in the pathologic condition and in the prognosis with diametrically opposed principles of treatment is at the proximal end of the radius. Fracture of the radial head in the adult is frequently comminuted with involve-

From the Fracture Service of the Milwaukee Children's Hospital.

ment of the cup shaped articular portion. In the child there is usually a fracture through the neck with more or less displacement of the entire unbroken radial head. In the adult it is generally wise to excise the fractured head when there is displacement of the fragments. Treatment of the slightly displaced radial head in a child requires no therapy other than brief immobilization. Displaced fractures usually require open reduction, but the head should never be resected (fig 1), always replaced. Eventual complete recovery may be expected in the child. Some residual disability may be expected in the adult.

A systematic study was made of all fractures occurring in children including end result studies at yearly intervals, many check-ups after closure of the epiphyses and some ten year studies. Two hundred and seventy-one fractures of the forearm were treated by the fracture service of the Milwaukee Children's Hospital in the period between 1935 and 1941 inclusive. Unusual and interesting cases were added from the private files of the attending surgeons. We have had the benefit of studying the end results of open reduction in the earlier Children's Hospital cases. The unpublished cases of colleagues who volunteered reports at the exhibits that have been conducted by the fracture service have disclosed the shocking occurrence of complications. This material has formed the basis for certain convictions which might sound dogmatic if they were not substantiated by clinical proof.

Fig 2 (case 2)—Anteroposterior and lateral views of the forearm at 11 years of age two months after an open reduction on the radius. The patient wore a splint for four months following the operation. The delayed union was not due to malposition but was definitely associated with the open reduction. Three years after the operation the patient still complained of pain and inability to play a violin or to engage in active sports. He gradually became symptom free after four years.

With the exception of the radial head, which frequently requires open reduction according to the technic so well described by Key,² we have found almost no fracture in the forearm which cannot be treated better

by closed methods than by open. When open operations have been done elsewhere there have been instances of nonunion or other complications to report. In our old files we have no example of nonunion following open reduction in the forearm but several of malunion and delayed union (fig 2).

With fractures of the forearm in adults accurate reduction is most desirable and open operation is not

Fig 3 (case 3)—Refracture of the middle third of both bones of the right forearm with gross displacement.

infrequently necessary. In children under 12 years of age accurate reduction is desirable but good apposition is not essential. It is amazing to read an article published as late as September 1941 advocating anatomic reposition.³ The younger the child and the nearer the end of the bone the more leeway one has. A perfect functional result and after a year a perfect anatomic result will ensue without any apposition in a young child as long as the alignment is reasonably good. In such a case even the alignment need not be good in fractures of the distal end of the bone. In fractures of the middle third of the forearm accurate alignment is imperative, because growth does not so greatly influence angulation at this level. Persistent angulation will almost invariably result in some permanent limitation of pronation or supination.

FRACTURES OF THE UPPER THIRD OF THE FOREARM⁴

Fractures of the upper third of the forearm are relatively rare. They comprise 6.9 per cent of the forearm fractures in our series. They are frequently caused by direct trauma. Sometimes only one bone is fractured, but care should be taken to distinguish the characteristic association, which will be discussed later, of a dislocation of the radial head with fracture of the

³ Thorndike Augustus Jr and Dimmler Charles I Jr Fractures of the Forearm and Elbow in Children New England J Med 225 475 (Sept 25) 1941

⁴ Fractures of the radial head will be discussed at a later date under the title Fractures About the Elbow.

² Key J Albert Treatment of Fractures of the Head and Neck of the Radius J A M A 96 101 (Jan 10) 1939

proximal end of the ulna. The diagnosis offers no difficulty if roentgenograms are taken of both elbows, but a greenstick fracture is otherwise occasionally overlooked or confused with an epiphysis.

Fractures of both bones of the upper third of the forearm in children as in adults are difficult to reduce accurately. The problem of the strong pull of the pronator radii teres on the distal fragment is the same. In general, the fracture should be reduced and reduction maintained with the distal portion of the forearm supinated in an attempt to align the distal fragments with the proximal, which are strongly influenced by the supinator muscle and the biceps. This position alone combined with traction will usually suffice to align and appose the fragments accurately. Apposition is not as necessary as it is in adults. Alinement is essential, but if the ends of the bones are not engaged it can easily be maintained by skin traction on the hand. Decolage, or intrinsic rotary displacement of the radius, was emphasized by Destot⁶ as a factor in producing limitation of pronation in adults. In children, rotational deformity frequently persists for several months but will entirely disappear after that time in fractures of the upper third of the forearm.

A lightly padded cast from the axilla to the knuckles with the elbow in an extension of 120 degrees and the forearm completely supinated is usually adequate treatment. It should remain on at least four weeks. If there is overriding of the bones without apposition of the fragments to control length, banjo traction on the fingers should be added.

Fig 4 (case 3)—Appearance of the bones six months after simple cast fixation with good alinement but no apposition. There is slight restriction of pronation and supination.

FRACTURES OF THE MIDDLE THIRD OF THE FOREARM

Fractures at the middle of the forearm occur more frequently than those of the upper third and in our series comprise 17.7 per cent of the forearm fractures.

They usually involve both bones, although a single bone is more commonly fractured in children than in adults. This was the radius in 91 cases and the ulna in 17. Although indirect force will occasionally break only one bone, such a fracture is usually caused by direct violence.

Fractures of both bones with displacement are frequently very difficult to reduce. Open operation was used occasionally in the earlier cases but is difficult to

Fig 5 (case 3)—Appearance four years later. Clinically and roentgenologically the left forearm is indistinguishable from the right.

justify in the light of our experience (figs 3, 4 and 5). In the middle third alinement is most important, apposition less so. "Bayonet" apposition is satisfactory. Shortening is not desirable but is not of permanent consequence. Even a small amount of angulation will result in cases of prolonged healing and, in older children, permanent limitation of pronation and supination. In a young child this limitation of rotation causes very little inconvenience but is none the less a deformity.

Since the day of Hippocrates there has been and still is an active discussion of the degree of supination in which forearm fractures should be immobilized. Hippocrates⁶ warned against supination and advocated midposition or slight pronation, while Pare⁷ urged midposition. At first no differentiation was made as to level. Most of the early writers, including Malgaigne,⁸ Volkmann,⁹ Destot,¹⁰ Helferich,¹¹ Lonsdale¹² and Ashhurst,¹³ advocated supination even for fractures of the distal end. Their choice of position was influenced in

part by the use of wooden splints. Since the advent of plaster of paris and the roentgenogram, midposition is usually selected for fractures of the middle third.

If there is overriding of the bones a simple cast or splint is not satisfactory for preservation of the length and alignment. We recommend traction with a banjo

Fig 6 (case 4)—Anteroposterior and lateral views of the left wrist of a 5 year old boy following unsuccessful attempts at closed reduction.

splint incorporated in a cast as the ideal treatment if reduction cannot be accomplished.

Refracture of the two bones at the same site as the original fracture is very frequent during the first six months after the original fracture. Cross union, which was mentioned by Cole and Evans,¹⁴ has not been observed by us.

An isolated fracture of the radius or ulna in the middle third of the forearm of an older child will occasionally defy reduction by closed methods. The angulation cannot be overcome because of the effect of the sound bone. If the complete displacement is associated with considerable angulation, the deformity will be apparent for a long time. There is a definite hazard of permanent limitation of pronation or supination. In such a case, and under ideal conditions, open reduction may be justified. Internal fixation is not necessary. With conservative treatment the end result will be a nearly normal forearm with no subjective symptoms or any significant restriction of movement. One should, therefore, urge that a conservative course be followed unless there is an ideal opportunity for open reduction.

A greenstick fracture of one or both of the fractured bones is frequently encountered in children. If such an incomplete fracture is bent just straight, as has been recommended elsewhere,¹⁴ the bone is liable to angulate again into deformity during the first two weeks of immobilization. This recurrence appears to be associated with both the muscle pull and the deposition of callus. With attempts to maintain incomplete reduc-

tion by pressure pads or lead pencils incorporated into plaster, we have seen pressure sores and even Volkmann's contracture.

If both bones are broken entirely through, as recommended originally by Malgaigne,⁸ retention is easy. We have never seen any displacement of fragments associated with this procedure which has been carried out routinely in all greenstick fractures. The completion of the fracture is accompanied by a loud snap. The maneuver may be performed without anesthesia within the first hour or two after the injury with very little discomfort other than a momentary twinge of pain. After a longer time has elapsed, an anesthetic is desirable. Fixation should include the elbow. A cast from the axilla to the knuckles with the forearm in mid supination and the elbow flexed to 100 degrees is an ideal dressing. The cast should remain on at least four weeks.

MONTGOMERY'S FRACTURE

An isolated fracture of the ulna with dislocation of the radial head occurred only three times in our series. It is usually caused by a fall on the outstretched hand but it may be caused by direct force. The diagnosis offers difficulty only in that in children the dislocation of the radial head may be overlooked. Accurate roentgenograms are essential, and the opposite elbow should be included.

If seen promptly, such a fracture may usually be reduced by the closed method. When the dislocation

Fig 7 (case 4)—Appearance after application of a traction cast with out the use of an anesthetic.

is reduced the radius serves as a splint and the ulna is frequently pulled into position and requires no fixation other than the supportive dressing which is applied to the elbow. The collar and cuff method of Sir Robert Jones is a good one for maintaining flexion. An elastic bandage about the elbow will prevent swelling and will give some support. Occasionally there will be angulation which cannot be overcome. It has never been seen to a degree sufficient to warrant open reduction. In

cases several days old and occasionally in fresh ones it is impossible to reduce the dislocated radial head without open operation. Open operation is then necessary for reduction of the radial head and reconstruction of the orbicular ligament. In 1 of the early cases, the dislocation was overlooked and an open reduction

Fig 8 (case 4)—Anteroposterior and lateral views of the left wrist five weeks after the fracture and at the time the traction cast was removed to be replaced by a simple splint. Note the complete displacement of both bones but with fair alignment and the massive callus. Compare with the inadequate callus at two months in figure 2.

done on the fractured ulna. Poor alignment was obtained but good bone union resulted. The appearance in the roentgenogram was bad. The ten year end result study showed excellent function, although the radial head was palpable and visible under the skin and moved around without hindrance. The child could throw a ball with his affected right hand, had no pain and had normal strength and range of motion. This almost incredible result is evidence of the fact that there is no need during childhood for removing the radial head. There have been numerous unreduced dislocations of the radial head observed in our series. Although the hypermobility of the radial head is distressing to the surgeon and to the parents, it apparently causes the child no inconvenience.

When the radial head is removed in a young child the inevitable sequel is a deformity of the wrist with radial deviation of the hand, shortening of the radius, weakness and sometimes pain (fig 2).

FRACTURES OF THE LOWER THIRD OF THE FOREARM

Greenstick fractures of the lower end of the radius with or without a greenstick fracture of the lower end of the ulna occur frequently with angulation of 5 degrees or less. These require no treatment other than brief splinting to relieve pain. Complete fractures or greenstick fractures with angulation of more than 10 degrees

should be reduced. When there is no loss of apposition, straightening the angle is a simple matter. There is a strong tendency to recurrence of the angulation with the apex volarward, however. This usually occurs in the first three days following reduction, probably mostly during the patient's recovery from anesthesia. Occasionally it has been necessary to reduce a fracture a second time at the end of ten days. Extreme volar flexion of the wrist (the so-called Cotton-Lodar position) has little effect in preventing this recurrence of deformity. Complete pronation of the forearm as advocated by Levinthal¹⁵ has been used in some of the cases but does not entirely overcome this difficulty.

Fractures in which both bones are completely displaced are frequently troublesome. If one bone, usually the ulna, is left in apposition, it may be used as a lever to reduce the other. If both bones are entirely off it is well to angulate the fragments with the apex volarward to 90 degrees, force the distal fragment down, engage one or both bones and then straighten out the angle as advocated by Lorie¹⁶. This can well be performed in pronation.

One can usually determine the position of the fragments by palpation. Fluoroscopic control is of value in fat children or in case swelling obscures the bony landmarks. The usual persistent deformity is dorsal displacement of the distal fragment of the radius. Occasionally this cannot be reduced by closed methods.

Fig 9 (case 4)—Showing normal appearance of the wrist at the time of removal of all fixation.

because of the interposition of muscle tissue between the bone ends. But this situation does not require open operation. A cast with simple traction to maintain alignment of the bones with bayonet apposition gives a

15 Levinthal D H. Fractures of the Lower One Third of Both Bones of the Forearm in Children. Manipulative Reduction Surg. Gynec & Obst 57:790 (Dec) 1933.

16 Lorie Jose Perez. A Manual Procedure for Setting Over Riding Fractures of the Lower Third of the Forearm in Children. La Revista Vida Nueva en el Numero Correspondiente 42 (Oct) 1938.

most satisfactory result (fig 7) Union is rapid Occasionally a clear zone surrounded by callus is evidence of the site of the muscle tissue This rapidly becomes calcified, however, and there seems to be no deleterious effect from the interposed muscle

There is a definite objection to open reduction While many surgeons have performed this operation with impunity many times on the lower end of the radius in children, a number have reported delayed union, nonunion or infection Nonunion requiring a bone graft is not infrequent It is common knowledge that a successful bone graft is often difficult to obtain in a child Delayed unions following open reductions are not uncommon The exact reason for this is not apparent Several theories have been offered such as interference with periosteal blood supply, removal of blood clot with its stimulating bone extract and simple mechanical interference with healing The fact remains that, with

Fig. 10 (case 4)—Anteroposterior and lateral views of the left wrist eight months after the fracture At the end of a year it was impossible to distinguish the fractured wrist from its fellow by roentgenograms

simple traction in a cast which is loose enough to avoid ischemia, even a badly displaced fracture of the lower end of both bones will result in good function

EPIPHYSIAL FRACTURES AT THE DISTAL END OF THE RADIUS

Fractures of the distal epiphysal line of the radius usually cause no difficulty Closed reduction is usually easy, and perfect alignment and apposition are the rule Slight angulation with only as much as 50 per cent apposition may be considered satisfactory The results are better with prompt reduction We prefer to leave an imperfect reduction rather than to attempt a delayed (ten days) reduction of such epiphysal fractures In cases in which treatment was given elsewhere, repeated trauma had apparently been a factor in producing growth disturbance from premature closure of the epiphysis Certainly growth disturbances are more frequent with open operation than with closed It is

significant that in the writings of such men as Cotton,¹⁷ who advised open reduction of distal epiphysal fractures of the radius, the incidence of gross bony deformity is rather high The old idea that accurate reduction is necessary to prevent growth disturbances must certainly be abandoned In our series of 16 cases, some of which were not completely reduced, there was no case of growth disturbance of more than 3 mm except for one of 5 mm of overgrowth In the interest of preserving the integrity of the epiphysal lines, delayed osteotomy should be considered in preference to a late open reduction

SUMMARY

1 Fractures of the forearm in children are different from those in adults and should be differently treated

2 There is a definite hazard associated with open reduction of fractures of the forearm in children

3 Except at the elbow, open reduction of forearm fractures is difficult to justify in children

4 Greenstick fractures of the middle third should be reduced by completing the fracture in the interest of maintaining alignment

5 The radial head should never be removed in a child

6 If conservatively treated, most epiphysal fractures of the distal end of the radius will heal without disability

Clinical Notes, Suggestions and New Instruments

VIRUS OF WESTERN EQUINE ENCEPHALITIS IN THE SPINAL FLUID

BRUCE CHOWN, M.D. AND MARJORIE NORRIS, B.Sc.
WINNIPEG, MAN., CANADA

Recovery of the virus from the cerebrospinal fluid of patients with encephalitis has rarely been reported There are only 2 reports of this in the medical literature¹

During the epidemic of western equine encephalitis in Manitoba in July and August 1941, positive results were obtained with the spinal fluid from a 6 weeks old baby admitted to the hospital on August 19 with fever and convulsions which had become apparent the previous day Lumbar puncture was done on admission The fluid was slightly cloudy and contained 998 cells per cubic millimeter, 80 per cent of which were polymorphonuclears There was a decided increase in globulin content Organisms were not found on smear or culture

On August 20, guinea pigs 1 and 2 each weighing approximately 300 Gm, were each injected intracerebrally with 0.2 cc of spinal fluid from this patient Guinea pig 2 remained well On August 26 the hindquarters of guinea pig 1 became paralyzed The animal was killed with ether and the brain removed aseptically One half was stored in sterile buffered glycerin solution The other half was ground up in a sterile mortar with sterile sand and sufficient sterile 0.9 per cent saline solution was added to make a dilution of approximately 1 in 100 After the emulsion had stood for an hour 0.2 cc of the upper part was injected intracerebrally into guinea pigs 3 and 4 Five days after injection August 31 guinea pig 3 was found dead The brain was removed and stored in sterile buffered glycerin solution Guinea pig 4 remained well

On September 2 a portion of the brain from guinea pig 1, which had been stored in glycerin was treated the same as the other half of the brain had been and 0.2 cc of the emulsion

injected into guinea pigs 5 and 6. Five days later guinea pig 5 had paralysis of the right hind limb and later in the day also paralysis of the left hind limb. On the same day guinea pig 6 had paralysis of the right hind limb. The following day there was a decided retraction of the muscles of the back in guinea pig 5. The animal was killed and the brain removed and placed in sterile buffered glycerin solution. For the next few days guinea pig 6 appeared to be recovering, but by the end of another week it became apparent that this was not the case. The animal was then killed and the brain stored in buffered glycerin.

A portion of the brain from guinea pig 1, stored in glycerin, was sent to Dr. H. R. Cox at the Rocky Mountain Laboratory in Montana, who isolated the virus of western equine encephalitis from it.

Blood was withdrawn from the patient on August 22 during the acute stage of the illness. The serum was sent to Dr. L. T. Webster at the Rockefeller Institute in New York City to be tested for complement fixing antibodies. The results were negative for the viruses of eastern and western equine encephalitis, St. Louis encephalitis and lymphocytic choriomeningitis. In a second specimen, taken September 6, the presence of complement fixing antibodies for western equine encephalitis was demonstrated, the results being negative for eastern equine encephalitis, St. Louis encephalitis and lymphocytic choriomeningitis.

A stool specimen was taken from the patient on August 26 for investigation by Dr. J. R. Paul of Yale University, no virus of poliomyelitis or of encephalitis was recovered.

A blood specimen, withdrawn October 2, was sent to Dr. Cox. In this he determined the presence of neutralizing antibodies for the virus of western equine encephalitis.

The baby made a complete recovery.

EXFOLIATIVE DERMATITIS DUE TO DIETHYLSTILBESTROL

LAMAN A. KASSELBERG, M.D., MEMPHIS, TENN.

Exfoliative dermatitis has been known to occur as a result of practically all types of medication; it is therefore to be expected that one should eventually encounter this dreaded reaction as a result of diethylstilbestrol therapy. Numerous toxic reactions to this drug have been reported. A number of these have been cutaneous.¹ Some have been severe and alarming.² However, in a careful search of the literature I have found no cases recorded of exfoliative dermatitis due to diethylstilbestrol. Because of the rarity and serious nature of this condition, I feel that this case is worthy of a report.

REPORT OF CASE

F. C., a woman aged 51, seen May 16, 1942, complained of hot flashes, nervousness and insomnia. These symptoms had become progressively worse for the past several years. The menses had been irregular for about three years and had ceased entirely six months before the patient was seen. The past history was without significance except for hypertension for several years. There was no personal or familial history of allergy. The patient was moderately obese and obviously very nervous. The blood pressure was 190 systolic and 100 diastolic, the temperature 98.6 F., the pulse rate 86 and the respiratory rate 18. There was moderate cardiac enlargement but no murmurs or arrhythmia. There were no cardiac symptoms and no other physical abnormalities. The Kahn reaction of the blood and urinalysis were negative. A diagnosis of menopausal syndrome was made, and she was

given 0.5 mg. of diethylstilbestrol intramuscularly and phenobarbital $\frac{1}{4}$ grain (0.016 Gm.) four times a day.

She returned in one week greatly improved, especially as to the nervousness and insomnia, and phenobarbital was discontinued. She was given diethylstilbestrol 1 mg. intramuscularly. She did not mention any cutaneous reaction or other toxic symptoms at this visit, but later questioning revealed that shortly after her first visit a generalized pruritus had developed, but she had believed it to be a 'heat rash' and did not consider it important. Her next visit was on May 30. She was again given 1 mg. of diethylstilbestrol intramuscularly. She again did not consider the 'heat rash' important.

June 2 I was called to see her and found her acutely ill. The temperature was 104 F., the pulse rate 108, the respiratory rate 30 and the blood pressure 170 systolic and 90 diastolic. She was in intense pain from the generalized and severe pruritus and there was a beginning generalized exfoliative dermatitis. The skin was hot to the touch, exfoliating and edematous—especially of the face and legs. There was generalized glandular enlargement. She was given boric acid, starch and soda baths and applications of calamine lotion and olive oil. Sodium thiosulfate was given by vein and by mouth. Calcium gluconate was given by mouth and large doses of vitamin B₁ were given hypodermically and by mouth. Codeine and phenobarbital were given to control pain and restlessness. Under this regimen she made a gradual recovery.

A patch test with diethylstilbestrol was negative in forty-eight hours. A scratch test gave a violent reaction with pseudopod formation, erythema, edema, pain and itching within twenty minutes. It was not thought safe or necessary to perform an intradermal test. All tests were given with the original undiluted diethylstilbestrol in sesame oil. Control tests with the pure oil gave negative results.

SUMMARY AND CONCLUSIONS

Diethylstilbestrol is an effective estrogenic medication but it causes many toxic reactions. Some of these may be violent and dangerous. It is therefore well to question and examine all patients thoroughly before continuing therapy. In this case it is believed that, had the early eruption been noted and properly evaluated, therapy would have been stopped and the exfoliative dermatitis avoided.

I believe that I have established the etiologic relationship between the diethylstilbestrol medication and the exfoliative dermatitis because of the positive scratch test and the negative reaction to the pure oil. Further, this hitherto nonallergic patient had taken no other therapy which could have caused this condition with the exception of phenobarbital and this had been discontinued for more than a week before the exfoliation began. In addition, phenobarbital was given during the height of the reaction for sedation and did not aggravate the disease.

Dermom Building

AURAL INFESTATION WITH SCREW WORMS

FREDERICK MILES TURNBULL, M.D., AND
I. BEN FRANKLIN, M.D., LOS ANGELES

The odor of decomposition is present in the discharges of many natural orifices, particularly if there is an accompanying suppuration. Stitt¹ points out that most flies instinctively deposit their eggs or larvae where there is the odor of decaying animal matter. A very common finding especially in warm climates, is that of fly larvae in the auditory meatus when there is otitis media and in the nasal cavity when ozena exists. Sarcophagic flies are widely distributed throughout the world and during war they are an important scourge; their larvae having been found in the wounds and body cavities of man.

On the American continent the fly *Cochliomyia americana* (syn. *hominivorax*) is common and the larvae are rarely found in dead and decaying flesh feeding as saprophyls but are associated with wounds in living animals.² These flies are usually primary invaders and cause extensive destruction of

2 Borgstrom Florene A. Experimental *Cochliomyia americana* Infestations with Special Reference to Bacterial Flora and Development of Immunity. *Am. J. Trop. Med.* 18: 395 (July) 1938.

living tissue. When the larvae invade the skin³ they produce festering, frequently deep, disfiguring wounds. Death has sometimes followed as a result of the lesions produced by these larvae, and Cushing and Patton⁴ reported an 8 per cent mortality in 179 cases studied by them.

REPORT OF CASE

Mrs. F. D., a white woman aged 60, with chronic suppuration of the middle ear and mastoid, was walking across a grassy field at Bryce Canyon, Utah, about noon on Aug. 21, 1941. An insect flew into her right ear and, so far as she could recall, remained there approximately two hours before she felt it leave, at which time the buzzing sound, which had been continuous, ceased.

About midnight of the same day she was awakened from sleep by resumption of the buzzing. At this time a watery, bloody discharge was emanating from the infected ear. The buzzing continued until 3 o'clock that afternoon, when one of us (L. B. F.) saw her at the Grand Canyon Lodge. On examination a white larva was observed in her ear. By irrigation four larvae were obtained, each about 3 mm. long, and the buzzing stopped.

Two hours later the buzzing started once more, and four more larvae were obtained. Later that evening nine more larvae were flushed out, together with some heavy granular pus. The external auditory canal was inspected and found to be clean.

During that same night and the following day (August 23) the ear was irrigated several times, and thirteen more larvae were obtained. These must have come from the mastoid cells, since the ear was clean after each irrigation.

At 5 o'clock on the morning of August 24 the buzzing sounds, which had been continuous, increased to a roar, and five more larvae were obtained after several irrigations. These larvae were now 1 cm. long and covered with setae, and blood could be seen inside them.

Fig. 1—Appearance of mastoid after all the worms were removed. Note the bony destruction from chronic suppuration, also partly from action of larvae, which was accompanied by bloody discharge from the mastoid.

The patient then left for Los Angeles by train. En route, the stewardess irrigated the ear once and obtained one larva.

Early on the morning of August 25 the patient came to one of us (F. M. T.) for treatment. Chloroform fumes were

used to anesthetize and kill the worms. This was accomplished by using the chloroform in the spray bottle under air pressure with a nozzle that fitted tightly into the external auditory canal. Three more larvae were thus obtained with irrigation, making a total of thirty-nine. To date, outside of possible bone destruction (fig. 1) the patient seems to have suffered no other ill effects from her experience.

Fig. 2—Mature larvae obtained on the fourth day after infestation.

COMMENT

The larvae (figs. 2 and 3) obtained from the ear of Mrs. F. D. were identified by Dr. W. Dwight Pierce, entomologist, of the Los Angeles Museum of History, Science, and Art, as primary screw worms of *Cochliomyia americana* (syn. *hominivorax*).

Cochliomyia americana is a greenish blue calliphorine species, an obligatory parasite of warm-blooded animals, breeding only in nature on living animals and capable of penetrating unbroken skin. Knippling and Rainwater⁵ found this fly in 90 per cent of 901 myiasis-producing wounds of man and animals in the middle, western and southern parts of the United States. The adults have a flight range of at least 9 miles and in a single summer may migrate as far as 1,500 miles north of the overwintering zone. The eggs are deposited in batches on injured or unbroken skin. The larvae hatch in from six to eight hours and feed ravenously on the liquid exudates of the wounds and penetrate by means of their powerful oral hoods. In the nasal or oral cavities the larvae may burrow into tissues, devouring in their passage mucous membrane, muscle, cartilage, periosteum and even bone. They may penetrate to the brain and cause death.⁶ The mature larvae are usually about $\frac{3}{8}$ inch long and have twelve rings of minute spines which make them resemble a

⁶ Manson-Bahr, P. H. *Manson's Tropical Diseases*, ed. 11, Baltimore, Williams & Wilkins Company, 1940, p. 850.

screw Borgstrom, in her experiments with this species, reported that eight larvae were the maximum which could be harbored in a guinea pig without resulting in the death of the animal.

Napoleon's famous surgeon, Dr Larry, noted the beneficial effects of certain maggots, namely those of *Lucilia sericata* and *Phormia* (common blow flies). The healing effects of these larvae have been ascribed to their ingestion of necrotic tissue, to their predigestion of such tissue by the tryptase present in the excreta, which becomes active in the presence of calcium carbonate exuded through the body wall, and in the alkaline reaction caused by ammonia in the excreta. Robinson⁷ demonstrated that the substance allantoin, which is a constituent of the urinary secretions of these maggots, stimulates healing in slowly suppurative wounds. It has been demonstrated that allantoin from other sources has this same stimulating action in the absence of maggots.

It is unfortunate, however, that the large majority of fly larvae that infest man and animals are capable of producing unpleasant, frequently serious and occasionally fatal results.

SUMMARY AND CONCLUSIONS

Cochliomya americana (syn *hominivorax*) is a fly common on the American continent. The larvae are frequently deposited in wounds on living animals and in man. The resultant lesions can produce frightful injury, and a mortality of 8 per cent has been reported. Although the fly is capable of penetrating unbroken skin, the odor of suppuration attracts oviposition.

Fig. 3—A few of the larvae obtained at intervals from the patient's ear showing various stages of maturity.

Patients with otitis media should be advised to keep cotton plugs in their ears while outdoors or around animals.

The larvae are readily killed by chloroform, and this should be used early in the form of vapor if possible or in fluid form if necessary.

PROCUREMENT OF BLOOD FOR THE ARMED FORCES

CLINICAL LECTURE AT ATLANTIC CITY SESSION

EARL S. TAYLOR, MD

National Technical Consultant Blood Donor Service American Red Cross
NEW YORK

In May 1941 the American Red Cross and the Division of Medical Sciences of the National Research Council were asked by the Surgeon Generals of the Army and Navy to organize a cooperative project for the collection of human blood plasma for the armed forces. The Red Cross was to procure the donors, while the National Research Council was to assume general supervision of the professional services and to provide for competent professional personnel. The technical aspects of the program were designed to comply with the requirements of the National Institute of Health. Based on the experience obtained at a pilot bleeding center in New York City, established in February 1941, this project has now expanded from coast to coast, and blood donor centers are now operating in seventeen cities. I have previously reported¹ the experience of this pilot unit with its first 10,000 donors. The methods and technique of blood procurement outlined in that report are in general those now employed in all the centers.

This blood plasma project had experience with 320,442 donors as of May 1, 1942, as shown in the accompanying table. Except for mass vaccination and inoculation projects this is the largest controlled medical effort that has ever been undertaken in this country. As this work will include between two and three million more persons in the next twelve months, it was felt imperative that the methods of procedure employed and the results obtained be presented to the medical profession. The continued success of the project depends on the thorough understanding of the operation of the service by the physicians of the country.

Because of the widespread publicity that plasma and other blood substitutes have enjoyed there has been some confusion as to the organization and the manner in which these blood donor centers have been set up. In order to clarify this it should be noted that the American Red Cross Blood Donor Service is the sole agency for procurement of blood to be used by the armed forces.² Furthermore, the centers of this service are the only agencies in which blood is obtained for the preparation of dried plasma for the Office of Civilian Defense.

The seventeen centers now in operation were chosen, first, because of their relation to centers of population and, second, because of their proximity to the commercial biologic laboratories that could process the blood into dried plasma. These considerations are necessary, for under the standards of the National Institute of

From the Presbyterian Hospital.

Read in the General Scientific Meetings at the Ninety Third Annual Session of the American Medical Association Atlantic City, N. J. June 9, 1942.

1 Taylor E. S. Blood Procurement for the Army and Navy, *J. A. M. A.* 117: 2123 (Dec. 20) 1941.

2 The American Red Cross in cooperation with the Army Medical Corps is opening several additional centers to procure liquid plasma for use solely in army general hospitals within continental United States.

Health the plasma must be carried to the frozen state within seventy-two hours after the blood has been withdrawn. Because of difficulties in transportation and refrigeration, it is not practicable to set up centers at great distances from the plants, particularly when sufficient blood can be obtained nearby. Seven processing plants are now in operation and three others are being added to accommodate the request of the Army and Navy for the production of albumin³ obtained from human plasma. Naturally such a plan of organization makes it impossible to include many communities in which the people generously wish to participate as blood donors.

It can easily be seen that, in a program of such magnitude, an assembly line type of production must be developed. This is necessary not only in order to produce in such large quantities but also because when

and manner of procedure in handling this large group of donors, every effort has been made to speed up efficient procedure. Each step has been made only after it has been fully determined whether, first, it incurs any risk to the donor and, second, whether it will in any way damage or impair the final product.

PROCEDURE

In order that the assembly line of production may be a smooth one it is necessary that a steady, even flow of donors be maintained. If a bleeding team is deluged with a number of donors beyond its capacity, proper care cannot be exercised in attending these donors. Similarly, if the capacity of the processing plant is exceeded, much of the blood may be wasted in the processing.

As the tempo of the war effort has stepped up, not the least difficult part of the program has been to control the enthusiasm of individuals and groups that wish to donate their blood. In this respect the mobile unit has been of inestimable value (fig. 1). It is used by sixteen of the seventeen centers and is at present the source of supply of 35 per cent of all the blood obtained. Through its use, small communities can be included in the program as autonomous groups. Factory workers can contribute without undue loss of time. Political fraternal union and neighborhood groups can make donations as units. From the point of view of civilian defense it should be noted that the bleedings taken each day at every center are available to that community in the event of a catastrophe caused by sabotage or other enemy action. Furthermore, the bleeding teams are on twenty-four hour call for emergencies and as a mobile unit can set up for operation in any locale within 75 miles of the blood donor center.

THE PROTECTION OF THE DONOR

From the outset of the program the protection afforded the donor has been of primary consideration. The minimum donor requirements have been set forth in a previous communication.¹ No extensive physical examination is given but instead a series of ten questions is asked. Temperature, hemoglobin, blood pressure and pulse determinations are made and on a basis of these findings and the history the physician decides whether or not the applicant is a suitable donor.

- 1 Age Donors 21 to 60 years of age inclusive are accepted.
- 2 Sex Both male and female donors are taken.
- 3 Race Members of all races are accepted.
- 4 Temperature A donor is not acceptable if the temperature by mouth exceeds 99.5 F.
- 5 Hemoglobin A donor is not acceptable unless the hemoglobin level is 80 per cent or above.
- 6 Blood Pressure A donor is not acceptable unless the systolic blood pressure is between 100 and 200 mm of mercury.
- 7 Pulse The pulse is to be recorded. Particular note is made of irregularity as well as decided bradycardia or tachycardia.
- 8 History The donor is asked the following questions:
 - 1 When did you last donate blood? (At least eight weeks must elapse between donations.)
 - 2 Have you had any illness in the last month?
 - 3 Have you ever had malaria? tuberculosis?
 - 4 Did you ever have shortness of breath?
 - 5 Have you had swelling of the feet?
 - 6 Have you had a persistent cough?

dealing with as fragile a biologic product as plasma, standardization of operation is absolutely essential. If this vast army of donors is to be adequately protected all details of technique and equipment must be uniform and made use of in a standardized manner. From an organizational point of view the bleeding is done by a team that consists of one doctor, a secretary, four nurses and one or two shipping clerks. The basis of operation of such a team is a unit consisting of two beds and a work table under the supervision of one nurse. A trained team can easily handle 100 donors in from four to five hours. These compact teams have enabled widespread extension of the work without the addition of a large number of physicians. About forty doctors, many of them women, are now bleeding over 20,000 donors per week. Although volunteers are used to assist in the work of each bleeding team, they are in no way concerned with the medical appraisal of the donor or the actual venesection. In evolving the technique

- 9 Do you have fainting spells?
- 10 Do you ever have convulsions?

9 Persons with diabetes are accepted only on written permission of their physician

10 No donors are accepted who are pregnant or who have delivered within the past nine months

Proof of the efficiency of the method of selection of donors needs no further comment than the fact that 286,197 donors have been bled without a single fatality or serious accident. This is far below the expected accident death rate in the population as a whole and can only mean that a highly selected group have been carefully handled both during and after venesection. Of the 320,442 persons who have offered to donate, 26,875, or 8.3 per cent have been rejected as not meeting the donor requirements. More prospective female donors are refused than male, the ratio being 1.193.

Accidents that can conceivably occur to the donor fall roughly into five main categories:

1 Cardiovascular disturbances. Two subjects with known heart disease were hospitalized for mild decompensation. Neither had admitted having heart disease on questioning before donating. A 54 year old male donor with no previous cardiac history had a coronary occlusion within the first twenty-four hours after donating. He was hospitalized and made a full recovery.

2 Infection about the site of the venipuncture. Only five infected arms have been noted. All infections were localized and responded rapidly to therapy. One donor was said to have developed transient staphylococcal septicemia forty-eight hours after being bled. He recovered after being hospitalized for five days.

3 Lacerations, contusions and so on associated with syncope. There have been fourteen head and scalp lacerations in donors who fell in syncope. One donor chipped a front tooth. A young man refusing to rest the prescribed length of time received a minor fracture of the clavicle when he fainted and fell against the bleeding couch. An elderly man was hospitalized for observation for possible concussion for forty-eight hours.

4 Burns, dermatitis and allergic reactions resulting from materials used in cleansing the arm. There have been no iodine burns. There have been 5 cases of dermatitis about the site of the venipuncture.

5 Miscellaneous. A few female donors have complained of delayed menses. Five cases of hysteria have required observation up to eight hours. Some donors have complained of weakness and lassitude for from two to eight days. All rumored reports of profound anemia and prostration developing in donors have been found groundless on investigation.

It can be seen then that the majority of complications of blood donations result from syncope. Rather uniformly throughout the country approximately 3.5 per cent of the donors show some type of reaction that requires them to rest longer than the prescribed period of ten minutes. About half of these show definite syncope with momentary loss of consciousness. In the latter group there has been observed a small number who show a syndrome in which loss of consciousness is accompanied by generalized convulsions, incontinence, cyanosis and in a very few cases rather striking tetany

with carpopedal spasm.⁴ Donors with this syndrome when seen for the first time were most disturbing but all rapidly responded to symptomatic treatment. Appropriate steps have been taken to provide for a more thorough study of these subjects. All the teams, whether at the center or on a mobile trip have with them equipment to administer intravenous saline solution and drugs for sedation and stimulation. Considerable attention⁵ has been paid to this question of syncope and its prevention.⁶ The young adult of asthenic habitus who weighs but 100 to 110 pounds (45 to 50 Kg) is the most susceptible. If he has hypotension he is almost sure to have some reaction. One must also be on the lookout for the donor who has just worked a long shift at a factory, particularly during the warm weather when dehydration may be an added factor in predisposing to syncope.

At the beginning of the project it was felt necessary to keep each donor in a separate cubicle and out of sight of the other donors because of the importance of

Fig 1—A mobile unit in operation in an office building. All the equipment necessary including refrigerator and beds is transported in a 1 ton standard truck.

the psychogenic factors involved in syncope. Most of the centers have now adopted the open common bleeding room where all the donors are in full view of each other (fig 2). In this way the physician in charge can keep a close check on all of the donors in the room and be on the alert for any signs of impending reaction. It is important from a psychological point of view that an unburied, cheerful air pervade the bleeding room. Many a donor has been "talked out" of having a reaction.

A serologic test is done on each donor who is bled. This places on the physician in charge of each center a public health responsibility. Because of the confidential nature of the information at no time should the results of the serologic tests or the medical record

card be accessible to any one but the professional staff. All bloods giving positive and questionably positive reactions are double checked before they are reported as "unsatisfactory." The word syphilis is never used in any communication between processing plant, physician and donor. Each donor with a positive serologic reaction is carefully followed according to the state public health laws. There have only been 1,667 reports of positive reactions to date, or 0.595 per cent of the total number of bleedings obtained.

Donors are permitted to return for a second donation after eight weeks have elapsed but are not allowed to give more than five donations in a year. This spacing of donations is in accordance with the work of Fowler and Barer,⁷ who found that at times 25 per cent of donors have not regenerated their hemoglobin completely at the end of eight weeks and suggest that hemoglobin determinations be made if a second bleeding is to be done at that time. Twelve per cent of the donors who were rejected had substandard hemoglobin levels.

Fig. 2—The type of large room that has been found to be most suitable in bleeding masses of donors.

A carefully controlled study of 100 male professional donors of the Blood Transfusion Association⁸ in New York over a number of years throws some interesting light on this question of redonations. These 100 donors gave 3,617 transfusions averaging 525 cc of blood over a period of four to fourteen years. The average duration of observation is seven years. These donors gave from 16 to 101 times during the time studied, or an average of 36 times per donor. They were required to rest one week between transfusions for every 100 cc of blood given. They had hemoglobin determinations made each month they gave blood and had a routine hemoglobin check-up every three months if they had not given blood.

None of these donors showed a significant failure to regenerate their hemoglobin at the end of this rest interval, and over a period of years little variation has been noted from the original hemoglobin reading. It is felt that this long term study adds further

to the evidence that there is no deleterious effect on healthy individuals who make repeated blood donations at stated intervals.

There is one other factor that has a direct bearing on the donor but perhaps has a more legal than medical implication. The American Red Cross has undertaken to have typed the blood of each donor and to report the type to him according to the international classification. Not only is this of personal interest to the donor but potentially it offers factories, unions and small communities a basis for a "walking blood bank." Every effort has been made to make this typing accurate and of high standard. However, with such a great volume of bloods to be typed occasional discrepancies do appear. The Red Cross has felt that it is necessary to note on the certificate stating the patient's type that the typing given to him should be used only as a tentative classification if the holder should be called on to give or receive a transfusion. It is hoped that with this proviso included these certificates will prove of value to the individual and the community and still not be a dangerous implement in the event that there has been a discrepancy in the typing.

PROTECTION OF THE BLOOD OBTAINED

The equipment used throughout the project is similar to that originally described as being employed at the pilot unit. The standard bottle is of 550 cc capacity, contains 50 cc of 4 per cent citrate solution and is an entirely "closed" system. The original stopper has been improved so that it has an overhanging lip or hood which lessens the likelihood of the bottle becoming uncorked. A simple new clamp has been devised which more efficiently seals off the rubber tubing at the completion of bleeding. This bleeding set has been shown by experience to be simple to clean and to assemble. It has a minimum of replaceable parts—practically nothing but the rubber tubing. The bottle itself has proved to be of very high quality, as is shown by the fact that only 126 bottles have been broken in shipment and but 842 cracked in centrifugation, an overall breakage loss of but 0.345 per cent. Several other types of bottles are purported to have been used in collecting blood for the armed forces. The pictured set (fig. 3) is the only bleeding set that has been employed in this project. A second type of bottle was employed for a short time but was found to be unsatisfactory for many reasons, and its use had to be discontinued. This statement is in no sense to be construed to mean that the set in use is the only type of equipment suitable to take blood. It is felt however, that this set is peculiarly adapted for this type of mass bleeding wherein large numbers of people must be efficiently handled with a small personnel and particularly when due attention must be given to the cost of handling and repossessing the set.

As this country is in a state of war, the possibility of sabotage must be borne in mind. Every effort has been made to protect the sterilized sets before use and the bottles of blood in transportation back to the processing laboratories.

It has been shown in this project that without any question large quantities of fresh blood can be trans-

7 Fowler W. M. and Barer Adelaide P. Rate of Hemoglobin Regeneration in Blood Donors J. A. M. A. 118: 421 (Feb. 7) 1942.
8 Katzen E. M. Personal communication to the author.

ported considerable distances without appreciable loss. Several of the bleeding centers ship by railway express nearly 500 miles every day. It must be emphasized that these remarks have to do with freshly drawn blood that is properly refrigerated. It has been proved that proper refrigeration over both short and long hauls is one of the most important factors in limiting the loss from hemolysis and bacterial contamination. Losses from hemolysis have been small but 0.569 per cent, or 1,591 units. All but 406 of these were lost as the result of freezing when inadequate shipping arrangements allowed the blood to be exposed for a considerable period of time to subzero weather. So-called Church containers with built-in racks have been used to transport the blood by express. Their very cumbersomeness has prevented unduly rough handling. When adequately precooled they have served admirably in maintaining low temperature ranges during the warm weather. Although mechanically controlled refrigeration would be ideal, the complexity and expense of such equipment is prohibitive.

Miscellaneous losses total 794 bleeding units, or 0.284 per cent. For the most part these losses were unpreventable. For example, a pool that contained blood from a donor who developed typhus had to be withdrawn. On several occasions weather conditions caused the blood to be held too long in shipment. Actually but little of this blood was discarded, as the plasma obtained from it was used in pilot bottles for testing moisture content, and the like, thereby conserving usable material which normally would have been used for such tests.

The maintenance of sterility is the greatest problem that has to be faced in a plasma program. The problem of bacterial contamination is not sufficiently emphasized in much of the current scientific and commercial literature. In order to maintain a low rate of contamination there cannot be the slightest break in technic or in the handling of the blood from the time the bleeding set is originally sterilized until the final dispensing unit is dried. It has been clearly shown that absolute standardization in the preparation of the sets, venesection, refrigeration and transportation of the blood must be adhered to and that the personnel both at the bleeding centers and at the processing plants must be highly trained and subject to a minimum of turnover. Losses from bacterial contamination to date total 6,260, or 2.26 per cent. As this figure includes all losses from the beginning of the project, during which period sixteen new centers and four new processing laboratories have been broken in, it is felt that losses in the next six months of operation will be less than half this amount. The figures that have been obtained for the last two months indicate that this improvement is already being realized.

Although not a technical consideration, the record keeping in the project is of prime importance. No one person is more of an intimate cog in this program than the secretary of each bleeding team, for it is on the proper serial numbering of the medical record, bleeding bottle and serologic tube that all subsequent handling of the blood is dependent. In order to reduce the human error as much as possible the manner of maintaining such records has been worked out so that there is as little transcription as possible. The medico-legal importance of accuracy in this respect is obvious.

In order to ascertain the number of persons necessary to be recruited for each thousand units of dried plasma required for the Army and Navy, it is necessary to review the losses incurred from all reasons. Eighty-three people in every thousand are rejected because they do not meet the donor requirements. Another 25 are unable to be bled because of technical difficulties. The over-all loss, preventable and otherwise occurring in the processing plants add another 40 per thousand. Since it takes something more than one bleeding to provide plasma for the final dispensing unit, which contains 300 cc of plasma citrate mixture, it was found on the average that 1,100 usable bleedings are necessary to fill 1,000 final containers. Thus, when all the losses are added up it seems that in order to provide 1,000 packages of dried plasma for the Armed Forces 1,248 persons must offer to donate their blood.

This report of the bleeding centers and the processing laboratories does not represent the performance of 1 or 2 individuals or organizations but is a result of the coordination of every person concerned with each step in procedure from the time the donor enters the bleeding

Fig. 3—The standard bleeding set before and after use

center until the finished package is turned over to the Army and Navy. It has only been through the loyal cooperation of physicians, secretaries, nurses, volunteer aides, expressmen and technical staffs at the various processing plants that this, the largest production of human biologic material in a single project the world has known, has been attained.

SUMMARY

1 The American Red Cross Blood Donor Service acting in cooperation with the National Research Council is engaged in the largest controlled medical project ever undertaken in this country. It has already dealt with 320,442 persons offering to donate their blood to be processed into dried plasma.

2 There have been 286,197 donors bled without a single fatality or serious accident. The necessity of standard equipment, technic and personnel is essential for efficient production and to protect the health of the donor as well as the quality of the product produced.

3 Taking into consideration losses from all sources, it has been found that in order to provide 1,000 finished units of dried plasma for the armed forces 1,248 persons must offer to give their blood.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

FOR SOME TIME THE COUNCIL HAS QUESTIONED THE USEFULNESS OF SODIUM THIOSULFATE. NO STATEMENT OF ACTIONS AND USES IS INCLUDED IN NEW AND NONOFFICIAL REMEDIES SINCE THE PRODUCT IS A PHARMACOPOLIC ONE. THE PREPARATIONS OF THE FOLLOWING FIRMS STAND ACCEPTED: ABBOTT LABORATORIES, THE EMERGENCY ANTIDOTE KIT COMPANY, ENCO PRODUCTS INC., FLINT, EATON & CO., THE MALTBIE CHEMICAL COMPANY, THE W. S. MERRELL COMPANY AND G. D. SEARLE & CO. INC. THE DRUG HAS BEEN ACCEPTED FOR NEW AND NONOFFICIAL REMEDIES AND USEFUL DRUGS MAINLY ON THE GROUNDS OF ITS REPUTED USEFULNESS IN THE TREATMENT OF ARSENICAL AND OTHER HEAVY METAL INTOXICATION. AT THE LAST MEETING OF THE COUNCIL IT WAS DECIDED THAT A REPORT ON THE PRESENT DAY USE OF THE DRUG IN DERMATOLOGIC AND SYPHILITIC PRACTICE BE PREPARED. AS A RESULT OF THE SUBSEQUENT REPORT WHICH WAS ADOPTED THE COUNCIL VOTED TO OMIT ALL ACCEPTED PREPARATIONS OF SODIUM THIOSULFATE FROM NEW AND NONOFFICIAL REMEDIES AND TO REVISE THE USEFUL DRUGS STATEMENT OF ACTIONS AND USES TO OBLITERATE RECOMMENDATIONS FOR USE IN MERCURIAL AND OTHER FORMS OF HEAVY METAL POISONING AND FURTHER TO DISABLER ITS USE IN ARSENICAL INTOXICATION. THE VARIOUS FIRMS CONCERNED WERE INFORMED OF THE COUNCIL'S ACTION AND ASKED IF THEY COULD PRESENT EVIDENCE TO JUSTIFY CONTINUED INCLUSION OF SODIUM THIOSULFATE DOSAGES IN NEW AND NONOFFICIAL REMEDIES. NONE OF THE FIRMS PRESENTED SUCH DATA. THE COUNCIL FINALLY VOTED TO OMIT THE ACCEPTED PREPARATIONS OF SODIUM THIOSULFATE FROM NEW AND NONOFFICIAL REMEDIES, TO REVISE THE USEFUL DRUGS STATEMENT OF ACTIONS AND USES AS STATED AND TO ADOPT THE FOLLOWING REPORT FOR PUBLICATION.

AUSTIN F. SMITH, M.D., Acting Secretary

SODIUM THIOSULFATE OMITTED FROM N. N. R.

Sulfur containing compounds were recommended for treating arsenical reactions as early as 1916. In 1923 McBride and Dennie¹ reported beneficial results from use of sodium thiosulfate in 7 cases of acute and chronic arsenical and mercurial complications. Their theory was that the compound converted salts of arsenic, mercury, lead, bismuth, zinc and copper into nontoxic insoluble sulfides. Later they adopted the hypothesis that sodium thiosulfate will neutralize the metallic poisons free in the intestinal tract and render soluble and excretable those substances which have been taken up by the body and have been tightly bound by a protein radical.

Schamberg and Brown reported favorable results from the combination of thiosulfate with calcium in the form of calcium thiosulfate. Haag and Bond² found that both the oral and the intravenous use of the drug was valueless in poisoning produced by solution of potassium arsenite even though the supposed antidote was injected intravenously much more promptly than would be the case clinically. Stokes as long ago as 1934 was less convinced of the value of the drug in arsenical intoxication and stated that there might be actual damage if its use was continued after the first few days of an arsenopharmine dermatitis. Moreover, Moore,³ in the recent edition of his work, says on page 109 "Sodium thiosulfate is of no value in the treatment of arsenical dermatitis" and again on page 122 "Sodium thiosulfate is, so far as we can see, of no value at all in the treatment of arsenical jaundice or in any type of arsenical or mercury intoxication. Haskell, Henderson and Hamilton⁴ working with dogs poisoned by mercury bichloride, found sodium thiosulfate of no value as an antidote for the mercury that had gained entrance into the circulation.

Young and Taylor⁵ reported that sodium thiosulfate in large and repeated doses did not decrease the toxicity of mercury bichloride, of mercuric succinimide or of mercuric salicylate in rabbits. Nor did it decrease the tissue injury produced by the compounds studied.

5. Young A. G. and Taylor F. L. assisted by Elenor R. Shea. Effect of Sodium Thiosulfate on Mercury Poisoning. *J. Pharmacol. & Exper. Therap.* 42: 185 1931.

Rosenthal⁶ reported that sodium thiosulfate protected rats testes against the action of mercury only if added before the mercury. There was protection of the liver if the sodium thiosulfate was added either before or immediately after the mercury. No protection of the kidney was observed in any case. Injected intravenously into rats, sodium thiosulfate did not protect against a subsequent injection of mercury.

Oppenheim and Frant⁷ found sodium thiosulfate of no value in mice poisoned with arsenic trioxide. Animals receiving lethal doses of neorsphenamine were not benefited by it.

INFLUENCE OF SODIUM THIOSULFATE ON THE TRYPAONICIDAL AND SPIROCHETICIDAL ACTIVITY OF ARSEFICALS

Harrison⁸ quotes Dale's statement that "so far as our experimental trials have proceeded there is no indication that dissolving the neorsphenamine preparation before injection in a 25 per cent solution of sodium thiosulfate has any deleterious effect on the therapeutic action of the particular preparation on trypanosomiasis in mice." Voegtlin and Dyer⁹ reported that large doses of sodium thiosulfate did not decrease the trypanocidal efficiency of arsenopharmine, neorsphenamine or sulfarsphenamine and did not decrease the spirocheticidal action of sulfarsphenamine. The senior author¹⁰ had already shown that the compound has a very low toxicity. Myers, Groehl and Metz¹¹ had also found the same to be true in the therapeutic action of arsenopharmine on *Trypanosoma equiperdum*.

INFLUENCE OF SODIUM THIOSULFATE ON THE EXCRETION OF ARSENIC

Myers, Groehl and Metz¹¹ and Myers, Marples, Groehl and Throne¹² observed that patients with arsenopharmine dermatitis or jaundice under the influence of sodium thiosulfate excrete a large amount of arsenic in the urine, which they attributed in part to the removal of the stored arsenic from the body. On the other hand, Mattee, Baxt and Byrne¹³ found no evidence that sodium thiosulfate injected intravenously mobilized arsenic from body stores for urinary elimination. In fact, when an arsenical and thiosulfate are injected within an hour of each other in the order stated, they found the urinary excretion of the arsenic to be decidedly suppressed. Kuhn and Loevenhart¹⁴ found that sodium thiosulfate does not mobilize the arsenic in the body but seems to cause its transformation into a less toxic, less therapeutically efficient and less easily excretable product. Oppenheim and Frant⁷ also found no increase in urinary excretion of arsenic after use of sodium thiosulfate in a variety of dermatoses where solution of potassium arsenite, neorsphenamine and arsenic pills had been administered. In fact they call attention to the variation in arsenic excretion. This variation was also noted by Kuhn and Reese¹⁵. The administration of the thiosulfate resulted sometimes in increases and sometimes in decreases. Pronounced increases were of short duration and could not be maintained by subsequent doses of sodium thiosulfate. Peaks in rate of excretion were always several days apart, even with daily doses of the thiosulfate. Their clinical observations of the value of thiosulfate were not con-

vincing. Of course, Mattice and Weisman¹⁶ have already pointed out that arsenic excretion studies are valueless unless the diet is known.

ACTION OF SODIUM THIOSULFATE

Muir, Stenhouse and Becker¹⁷ think the therapeutic effects of the drug can be placed first under its action as a reducing agent, as suggested by Ravaut. Second, Curtis and Young,¹⁸ in their studies on the effect of sodium thiosulfate on the excretion of lead, decided that any slight effect was due to its alkaline reaction and not to any ability to form soluble or insoluble lead compounds. Shaffer¹⁹ also thinks that it has a tendency to produce an alkalosis, particularly if it is used indefinitely. Curtis and Young also questioned the conclusion of Frazier²⁰ in 2 cases in which an acute purpuric vesiculobullous dermatitis accompanied by fever had appeared following the use of an aqueous solution of sodium thiosulfate in the treatment of arsenical dermatitis. One of the patients also developed bronchopneumonia with pleural effusion and acute hemorrhagic nephritis. These investigators point out that sodium thiosulfate in an aqueous solution is a rather unstable compound and that heating it for forty-five minutes at 45 pounds steam pressure may have caused decomposition. They also point out that sodium thiosulfate ($\text{Na}_2\text{S}_2\text{O}_3$) is also known as sodium hyposulfite but that the American Chemical Society reserves this name for a more toxic compound, $\text{Na}_2\text{S}_2\text{O}_4$. Frazier incidentally had observed favorable results from the use of sodium thiosulfate in 3 further cases of arsenphenamine dermatitis. Myers and his co-workers¹² think that it causes a stimulation of diuresis. Baba²¹ found that it had no neutralizing effect against arsenphenamine but that it had a diuretic action.

There is difference of opinion as to whether sodium thiosulfate forms less toxic metallic sulfides. This was the opinion of McBride and Dennie. However, Hesse²² points out that the possibility of curing a metallic poisoning by way of the sulfide is limited because of the difference in toxicity of different metallic sulfides. No common rule will cover all of them. Each one must be tried out by itself. Hesse did find that various sulfur compounds were of no value in parenteral arsenic poisoning. Moreover, Lehner²³ has shown that sodium thiosulfate solution dissolves in neoarsphenamine solution without any precipitate.

Oppenheim and Fantl¹ think that the value of thiosulfate is due to its activating effect on protoplasm through splitting off of sulfur in the organism.

The referee submits the following summary of a careful review and of experimental work done by Muir, Stenhouse and Becker¹⁷ on 'The Action of Sulfur Containing Compounds in Arsenical and Mercurial Poisoning.'

The literature is reviewed relative to the clinical and experimental evidence for the value and action of sodium thiosulfate and other sulfur bearing compounds and sodium formaldehyde sulfoxylate in poisoning by various metallic salts, especially arsenic and mercury.

Studies carried out on 123 rabbits poisoned with inorganic and organic arsenicals and mercury failed to show any protective action of sodium thiosulfate and of sodium p-sulphydryl phenyl sulfonate, as used in various ways. Microscopic examination of the kidneys of animals poisoned by sodium arsenate showed the same degree of degeneration regardless of whether sodium thiosulfate or sodium p-sulphydryl phenyl sulfonate had been given.

Analysis of the possible modes of action of sodium thiosulfate—reduction, alkalization, diuresis, formation of less toxic metallic sulfides, rendering metallic salts soluble and excretable and intravital formation of sulfur—suggests the probable action of intravital formation of sulfur, a substance which has long been used in the treatment of metallic intoxication.

Theoretically, sodium p-sulphydryl phenyl sulfonate should have a more definite action on arsenicals because of its sulphydryl group, but this was not demonstrated in the experiments performed.

Sodium formaldehyde sulfoxylate protected rabbits poisoned with mercury bichloride only when given before the latter and not when given afterward. It had no protective action against poisoning by inorganic and organic arsenicals, regardless of whether it was given before or afterward.

Sodium formaldehyde sulfoxylate acts by reducing mercury bichloride to metallic mercury, which is considerably less toxic. It protects only by the intravenous route. When the mercurial salt is given by mouth, the protective drug must be administered only a few minutes thereafter. If the latter is given orally for mercurial poisoning by ingestion, it should be given with sodium bicarbonate to counteract the effect of the gastric acid, which delays reduction of mercury salts.

CONCLUSIONS AND RECOMMENDATIONS

It is quite apparent from experimental evidence at least that sodium thiosulfate is of no value in the treatment of arsenical and other heavy metal intoxication. Even its use in the early stages of arsenical intoxication is very questionable. While it is true that the literature is replete with case reports of various arsenical intoxications, particularly dermatoses, in which the drug seemed to be of some worth, yet it must be remembered that certain of these cases would have responded to simple rest in bed and hygienic provisions. It is quite difficult to control such clinical material.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

SATURDAY SEPTEMBER 12 1942

THE BIOLOGIC VALUE OF WHEAT PROTEINS

The war has focused attention on food, particularly such basic foods as wheat. Much has been said about the vitamin of wheat but relatively little of its protein content. Yet protein is just as necessary for life as vitamins perhaps and even more so because more of it is required to maintain health and efficiency. A thorough and conclusive study of the biologic value of the proteins contained in wheat flours is not only timely but of great importance in meeting the war time needs. Such an investigation has been recently reported by Harriette Chick¹ from the Division of Nutrition of the Lister Institute. The results of this investigation show much less variation and the results are much more conclusive than those of previous studies. Moreover, in no other experiments were all studies made on different flours derived from the same sample of wheat.

Dr. Chick has studied three wheat flours, each prepared from the same sample of grain. The method of study was as follows. Growth of young litter-mate rats, shortly after weaning, was compared on a diet whose sole protein content was derived from the wheat flour to be investigated. The rest of the diet was adequate in vitamins, minerals and fats. The three flours represented varying degrees of extraction of the whole meal, the first of which contained all of the grain and therefore was called 100 per cent. The second sample was designated as "National Wheatmeal," which contained 85 per cent of the wheat grain. The third flour investigated was that used for making ordinary white bread and represented about 75 per cent of the whole grain. Other wheat flours were not investigated, i.e., the so-called patent white flours, which in many instances represent but 30 to 40 per cent of the grain.

The results of this investigation were striking and conclusive. When the rats were fed at a suboptimal level which would represent a sort of restricted ration,

the growth of all rats on the whole meal was distinctly and emphatically greater than on the "National Wheatmeal" and even more so than on white flour. In three separate experiments this advantage ranged from 50 to 60 per cent. If the results were calculated on the basis of their relative biologic value, which represents the relationship between the weight increase and the protein eaten, the results are also striking, i.e., the whole meal comes off with a figure of 1.60 to 1.71 as compared with the white flour figure of 1.33 to 1.46, with the value for the "National Wheatmeal" falling between these two values.

Dr. Chick also investigated the lessened digestibility of the whole meal over the other flours and found that the coefficient of digestibility of the whole meal protein was from 5 to 6 per cent less than that of the white flour. However, if this factor was taken into account in calculating the biologic value of the whole meal, its superiority in protein content becomes even more apparent. In other words, the biologic value of the digested part of this flour rises to a figure of 1.98 to 2.13 in contrast to white flour, which increased but slightly.

The reason for the superiority of whole meal is apparent from the well known facts concerning the protein contents of the various portions of the wheat grain. Although the endosperm or white part of the wheat comprises 83 per cent of the grain, its protein content (gluten) is but 11 per cent, whereas the bran, which constitutes 15 per cent of the grain, contains 18 per cent protein, while the germ, though but 1.5 per cent of the grain, contains 40 per cent protein. The gluten of white flour is known as a poor protein undoubtedly because of its inadequate content of certain essential amino acids which act as limiting factors in its utilization. The point to be emphasized is that the proteins of the germ are composed of amino acids, which are able to supplement those of the gluten and thus raise the biologic value of the mixture out of proportion to the amount added. The same is true of the proteins of the bran, although it is probable that much of its protein may be unavailable for human digestion.

The inferences to be drawn from this study are obvious and fit beautifully with the well known vitamin studies of the various fractions of wheat. If we are to utilize as efficiently as possible the protein contained in wheat grain, it would seem most advisable to retain as much as possible of the protein constituents. In this sense, therefore, any milling which leads to a loss of some of the important proteins of wheat is distinctly to be deplored. Unfortunately, color seems to play an important part in the acceptability of various wheat flours by the public. Perhaps by education the popular habits may become so adjusted as to take advantage of the superior value of the whole grain over any flour that is made by extracting and removing part of the essential protein, not to mention its vitamin content.

¹ Chick, Harriette. Biological Value of the Proteins Contained in Wheat Flours. *Lancet* 1: 405 (April 4) 1942.

GERMICIDAL PLASTICS

Perfection of self-sterilizing plastics that can be used for the production of food containers, drinking cups and similar utensils or as a durable antiseptic paint or varnish to coat other exposed surfaces is now reported from the Rare Metal Institute, California Institute of Technology¹

Extremely small quantities of ionized copper, silver or gold have remarkable germicidal powers. Silver was selected by the California metallurgists as most promising because of its relatively low toxicity and comparative cheapness. The feasibility of coating surfaces with metallic silver was first ruled out, since such surfaces are soon "disactivated" by the formation of surface films of protein or other germicidally inert compounds. In order to produce a surface not susceptible to this "disactivation," only a portion of the available silver ions should be present on the surface, with an abundant supply of reserve ions protected from deterioration but so located as to permit rapid surface replacement by outward diffusion. To accomplish this the reserve silver compounds should be incorporated in some plastic material having the desired rigidity and outward diffusion rate.

The only inexpensive durable substances with the required properties are certain organic resins or plastics currently used in the production of the newer varnishes or paints. Silver compounds can be incorporated in the unpolymerized resins or dissolved or dispersed in the solvent. The further incorporation of a neutral, opaque filling material is of advantage if the germicidal surface is to be exposed to light. The resulting mixture is a viscous fluid which can be applied by brush or by spray. The fluid hardens in situ by polymerization or evaporation, forming a surface that is tasteless, odorless and resistant to mechanical wear. The total quantity of silver which the material must contain varies with the intended use and desired degree of permanence. One Gm. of silver ions for 1,000 square centimeters of exposed surface is the heaviest type of varnish thus far developed.

The germicidal properties of such surfaces have been tested with a number of yeasts, molds and saprophytic bacteria. The test micro-organisms are suspended in distilled water, peptone water, sucrose solution, cider, milk or other desired medium, which is spread as a thin film over the test surface. At intervals samples of the film are removed by means of a sterile cotton swab, and the number of viable micro-organisms is determined by routine cultural methods. The germicidal efficiency of the surface is judged by the rate of decrease in the viable count. With the most efficient surface thus far prepared, 100 million of *Escherichia coli* per cubic centimeter of suspension fluid are killed

in less than one minute. Other surfaces require five or more minutes for total sterilization.

The rate of sterilization does not vary appreciably for the vegetative forms of different bacterial species. Spores, however, are less readily killed. *B. subtilis* spores, for example suspended in cider or sugar peptonic solution requiring fifteen to thirty minutes for a 95 per cent reduction in viable count. Surfaces are not appreciably impaired by repeated washing, until the plastic layer is completely removed by mechanical wear.

Thus far acid fast bacteria and pathogenic viruses have not been tested with the new germicidal plastics. The plastic is readily applicable to metal, glass and wood surfaces or absorbed in paper or cloth. It is resistant to acids, alkalis and boiling water but may be readily removed by certain organic solvents. Its predicted effects in controlling microbic infections, however, have not yet been confirmed experimentally or statistically.

Current Comment

RUBBER DERMATITIS

Facial dermatitis caused by rubber respirators has been reported by Petro,¹ who observed 16 cases among the personnel at one of the Royal Navy depots. The diagnosis of rubber dermatitis due to the wearing of masks was suspected on the ground that (1) the lesions showed a distribution which was mainly confined to areas of facial contact with the rubber face pieces, (2) symptoms and signs manifested themselves either for the first time or, if already present in an aggravated form on the day following respiratory exercise, (3) mild and evanescent symptoms, worse with each exercise, were admitted in retrospect by a number of patients, (4) some cases followed a recent change in type of respirator, (5) the masks bearing embossed lettering of certain firms alone were found responsible for the dermatitis and (6) patch tests with rubber disks cut from the patients' respirators and applied to their forearms showed positive reactions. Schwartz and Tulipan² point out that most of the cases of dermatitis observed by them in the rubber industry were due, not to the rubber itself but to the accelerators and the antioxidants used in the manufacture of rubber. Among the accelerators used, hexamethylenetetramine was the one found to cause the most dermatitis. The diagnosis in cases reported by Petro was confirmed by ascertaining the nature of all "accelerators" and "antioxidants" used in the manufacture of service masks and by finding their respective irritant properties in tests on sensitized subjects and normal controls. Two offending substances and their concentrations were found to be responsible for the dermatitis. The types of mask owned by the 16 patients were all found to be of a manufacture in which one or another of these irritant compounds had been used. From three to

¹ Petro, John. Respirator Dermatitis. *Brit. M. J.* 1: 631 (May 23) 1942.

² Schwartz, Louis, and Tulipan, Louis. *A Textbook of Occupational Diseases of the Skin*. Philadelphia: Lea & Febiger, 1939.

fifteen exposures to potentially harmful masks for fifteen minutes at weekly intervals were necessary for the production of sensitization in predisposed subjects. The degree of perspiration, depending on atmospheric temperature, humidity, exercise, diet and individual variation, proved an important predisposing factor. The lesions in the early stage were confined to areas of the face which came into close contact with the mask. When confluent, these had the appearance of an oval band of dermatitis surrounding a clear central portion of the face. The early erythema stage of dermatitis was followed by vesicular and weeping stages frequently associated with edema of the lax tissues which gave an appearance of puffiness and double chin. A deep-seated submental induration occurred in 4 cases. The patch test gave positive results in susceptible subjects only when these had become sensitized, consequently it was impossible to forecast susceptibility and to anticipate respirator dermatitis. Petro suggests that the most effective prophylactic measure would be to recall all the potentially harmful masks and to replace them by innocuous varieties.

COUNTY "ACCREDITATION"—A NEW IDEA IN HUMAN TUBERCULOSIS CONTROL

Tuberculin testing of cattle has come to be an accepted public health procedure in the United States. Testing of herds and eradication of reactives has progressed so that the entire continental area of the United States is now included in the so-called modified accredited area, that is areas in which reactives on retesting number less than 0.5 per cent of cattle tested. The Minnesota State Medical Association and the Minnesota Department of Health have begun accrediting counties for their endeavor and success in finding and controlling tuberculosis in human beings.¹ A set of standards has been established which requires an average death rate of less than 10 per hundred thousand of population and a rate of infection among high school seniors of less than 15 per cent, based on a recent tuberculosis testing survey. Extensive instructions are given as to how to check the detailed requirements, which include availability of adequate care in sanatoriums, a satisfactory case finding program, health education directed at discovery of early tuberculosis and provision of adequate treatment for its victims. In this project the medical profession, the sanatoriums, public health educators, county public health nurses, county commissioners, public health boards and the voluntary Christmas Seal organization are participating. Attractive certificates have been prepared, the first has been awarded to Lincoln County, a rural county located in southwestern Minnesota. This is signed by the state health officer, the president of the state medical society and the governor of the state. In addition, handsome distinguished service award plaques have been awarded to two Minnesota physicians for "achievement in human tuberculosis control" by "public health activities." Thus Minnesota pioneers in applying to the problem of human tuberculosis methods which have been successful

in eradicating tuberculosis among cattle. Since the human reactor must be educated whereas the bovine reactor is eliminated by slaughter the process will be slower, but the principles are sound.¹

AN EXTRAORDINARY CASE OF OBESITY

Excessive weight has long had extraordinary interest. Recently Willoughby,¹ in a survey of the literature, found only 16 instances of persons weighing 700 pounds or more. Of these, 10 were men and 6 were women. The heaviest man weighed more than 1,000 pounds and the heaviest woman reputedly weighed 850 pounds. His report of the case of a woman weighing more than 700 pounds is principally to present a formula of what he calls an index of "relative obesity" whereby fatness may be rated. In other words, the height must be considered as well as the weight so that the classification index relates the width of the body to the height. Judging by this index, Willoughby believes that the subject he reports, a 35 year old woman weighing about 800 pounds, is the fattest human being known at the present time and possibly of all time. The observations are based on the subject when weighing 772 pounds with a stature of 5 feet 5½ inches. This ratio of weight to height presents girth measurements which in general are 2.41 as great as those of a woman of medium build of the same height and in none of the 16 other subjects of known height which he was able to review is the index of relative obesity higher than 2.22. Willoughby believes it is evident that every possible favoring factor combined to produce this person's unique bulkiness of figure including heredity, exceptionally large appetite and likewise a constitutional metabolism that was abnormally efficient in producing and storing fat.

MEDICAL IMPERSONATION AS A MINOR CRIME

Elsewhere in this issue of *THE JOURNAL* (page 145) is one of the most amazing stories of medical imposture that has ever appeared in the pages of this publication. Over a period of twenty years this impostor continued a "vocation" of impersonating a physician in spite of intervening convictions and imprisonment. Following his most recent arrest he was given the maximum sentence in California for such practice. This sentence is six months in the county jail and a \$600 fine. A month later he was sentenced for illegal possession of firearms. His sentence for this crime was nine months in jail. This nine month sentence was not for shooting at some one or even aiming in the general direction of an innocent bystander but merely for the possession of a lethal weapon. The six month sentence resulted from his acting as chief assistant surgeon in a hospital. This would obviously include not just the possession of a scalpel but the use of one on unsuspecting patients. A comparison of the length of the two sentences emphasizes the ludicrous aspects, perhaps authorities will now institute legislation to make the punishment for practicing medicine without a license at least as serious as carrying a razor.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

POLICIES GOVERNING INITIAL APPOINTMENT OF MEDICAL OFFICERS

The Surgeon General of the Army published detailed information concerning policies governing the initial appointment of physicians as medical officers on April 23, 1942. Necessary changes are given wide publicity, at his request in order that the individual applicants, and all concerned in the procurement of medical officers, may know the status of such appointments.

The current military program provides for a definite number of position vacancies in the different grades. The number of such positions must necessarily determine the promotion of officers already on duty and, in addition, the appointment of new officers from civilian life. Such appointments are limited to qualified physicians required to fill the position vacancies for which no equally well qualified medical officers are available. Such positions calling for an increase in grade should as far as possible be filled by promotion of those already in the service and not by new appointments.

If this policy is not followed, it would definitely penalize a large number of well qualified lieutenants and captains already on duty by blocking their promotions which have been earned by hard work. In view of these facts it has been deemed necessary to raise the standards of training and experience for appointment in grades above that of first lieutenant.

With this in view, the Surgeon General has announced the following policy, which will govern action to be taken on all applicants after Sept 15, 1942.

All appointments will be recommended in the grade of first lieutenant with the following exceptions:

Captain—1 Eligible applicants between the ages of 37 and 45 will be considered for appointment in the grade of captain by reason of their age and general unclassified medical training and experience.

2 Below the age of 37 and above the age of 32, consideration for appointment in the grade of captain will be given to applicants who meet all of the following minimum requirements:

- (a) Graduation from an approved medical school
- (b) Internship of not less than one year, preferably of the rotating type
- (c) Special training consisting of three years residency in a recognized specialty
- (d) An additional period of not less than two years of study and/or practice limited to the specialty

3 Eligible applicants who previously held commissions in the grade of captain in the Medical Corps (Regular Army, National Guard of the United States, or Officers Reserve Corps) may be considered for appointment in that grade provided they have not passed the age of 45 years.

Major—1 Eligible applicants between the ages of 37 and 55 may be considered for appointment under the following conditions:

- (a) Graduation from an approved school
- (b) Internship of not less than one year, preferably of the rotating type
- (c) Special training consisting of three years residency in a recognized specialty
- (d) An additional period of not less than seven years of study and/or practice limited to the specialty
- (e) The existence of appropriate position vacancies
- (f) Additional training of a special nature of value to the military service, in lieu of the foregoing

2 Applicants previously commissioned as majors in the Medical Corps (Regular Army, National Guard of the United States or Officers Reserve Corps) whose training and experience qualify them for appropriate assignments may be considered for appointment in the grade of major provided they have not passed the age of 55.

Lieutenant Colonel and Colonel—In view of the small number of assignment vacancies for individuals of such grade, and the large number of reserve officers of these grades who are being called to duty, such appointments will be limited. Wherever possible, promotion of qualified officers on duty will be utilized to fill the position vacancies.

Much misunderstanding has arisen concerning recognition by specialty boards and membership in specialty groups. It will be noted that mention is not made of these in the preceding paragraphs. This is due to the variation in requirements of the different boards and organizations. Membership and recognition are definite factors in determining the professional background of the individual but are not the deciding factors, as so many physicians have been led to believe.

The action of the grading board, established by the Surgeon General in his office, is final in tendering initial appointments. Proper consideration must be given such factors as age, position vacancies, the functions of command and original assignments. All questionable initial grades are decided by this board. Owing to the lack of time, no reconsideration can be given.

There are in the age group 24-45 more than a sufficient number of eligible qualified physicians to meet the Medical Department requirements. It is on this age group that the Congress has imposed a definite obligation of military service through the medium of the Selective Service Act. The physicians in this group are ones needed now for active duty. The requirements are immediate and imperative. Applicants beyond 45 years may be considered for appointment only if they possess special qualifications for assignment to positions appropriate to the grade of major or above.

WOMEN PHYSICIANS RAISE \$2,000 FOR RELIEF FUND

Women physicians affiliated with the Luzerne County Medical Society in Pennsylvania who comprise the local branch of the Medical and Surgical Relief Committee of America, have sent to the committee headquarters in New York more than \$2,000 in addition to the medical supplies, surgical instruments and dental equipment. The funds were raised through the sale of the committee's mercy emblems. The women physicians were

assisted by the woman's auxiliary to the Luzerne County Medical Society by nurses in the local hospitals and by various alumni associations. The surgical instruments were collected from physicians, dentists and druggists throughout the county. The sale of emblems was conducted in Wilkes Barre, Plymouth, Wyoming, Luzerne, Dallas, Pittston, Nanticoke and Forty Fort. Dr. Marjorie E. Reed of Plymouth, Pa. is the national chairman of the women's activities of the Medical and Surgical Relief Committee of America.

SUGAR FOR ACUTELY ILL PATIENTS

The Office of Price Administration declared on August 27 that hospitals principally engaged in care of persons acutely ill will be able to provide patients the same amounts of sugar used last year, as a result of a change in the sugar rationing regulations. Amendment No. 9 to Rationing Order No. 3 authorizes hospitals of that kind to obtain 65 per cent of the sugar base they have established for meals and food services instead of 50 per cent as heretofore, starting with the September-October allotment period. Added to this will be the so called "bonus" allotment, amounting to 25 per cent of the base, which will be available to all classes of institutional users for the September-October period. Thus the hospital allotment, 65 per cent plus the 25 per cent "bonus," will amount to 90 per cent of the base for the September-October period. By holding down their use of sugar for non-patients (members of the staff and others who eat at the hospital) to the 75 per cent level to which restaurants or other eating places are limited in this period, the hospitals will have enough sugar to provide patients with the full amounts they allowed to patients a year ago.

To qualify for the bigger allotment, a hospital must show that it is principally engaged in the care of patients who are acutely ill and who temporarily live within the hospital for medical or surgical care. A hospital principally treating chronic cases or mental illnesses and an institution such as a rest home or sanatorium are not eligible. The effective date of the amendment was September 2.

GAS OFFICERS' INSTITUTE IN DETROIT

The Detroit Office of Civilian Defense sponsored a gas officers institute in that city August 18-September 3 which was attended by four hundred chemists who will be gas identification officers serving in the city's air raid defense program. The same instruction was given to fifty emergency medical officers and others from twenty-five cities in Michigan outside of Detroit and to fifty defense leaders from several other states in the Middle West. This expansion of the original scope of the instruction was made at the request of the War Department and the Michigan Council of Defense. In addition to those enrolled in the courses four hundred zone and sector wardens and hundreds of other employees were to have been trained in decontamination work. Most of the sessions were held at the Rackham Educational Memorial Building in Detroit and the laboratory experiments at Wayne University. The lecturers included Col. Ralph E. Tarbett, chief sanitary engineer of the Office of Civilian Defense, Washington, D. C.; Lieut. Col. Willard A. Johnston, head of the Chemical Warfare Service's civilian protection school at Purdue University; C. S. Schoepfle, chairman of the University of Michigan chemistry department; H. B. Cutter, associate professor, Wayne University; Dr. Frederick F. Yonkman of the Wayne University College of Medicine; William G. Frederick, chief chemist of the bureau of industrial hygiene, Detroit Department of Health; Albert G. Gassman and Francis F. Farley, University of Detroit chemistry instructors; and Edward J. Bird, professor of analytic chemistry, Wayne University.

MOUNT SINAI HOSPITAL UNIT RECEIVES FLAG

On August 28 at Mount Sinai Hospital, New York, World War I veterans of Base Hospital No. 3 presented an American flag to the new third U. S. Army General Hospital, the Mount Sinai Hospital Unit, which departed on September 1 for a period of training in the South preparatory to going overseas. Col. George Baehr, who is on leave of absence from Mount Sinai and is serving as chief medical officer of the Office of Civilian Defense in Washington, D. C., presented the flag to the new unit on behalf of his fellow veterans. Lieut. Col. Herman Lande of the new general hospital received the banner. The new hospital was presented also at this ceremony with a

check from the board of trustees to cover emergency and special needs and a check from the Mount Sinai staff alumni association to provide recreational features. The physicians on the staff of the third General Hospital on that day were Harold A. Abel, Edward J. Bassen, Edgar M. Bick, Simon Dack, Henry Doubilet, Morris Feresten, Leon Ginzburg, Moses N. Holland, Henry Horn, Edward C. Jemerin, Samuel Karchitz, Samuel H. Klein, Percy Klingenstein, Herman Lande, Gerson J. Lesnick, Hymen Levy, Jack H. Levy, Ralph E. Moloshok, Abraham Palmer, Abou D. Pollack, Herbert Pollack, I. Scotty Schapito, Gabriel P. Seley, Solomon Silver, Sidney M. Silverstone, Irving Solomon, Irving Sornach, Morris F. Steinberg, Moses Swick, Lester R. Tuchman, Robert I. Walter, Louis R. Wasserman, Edwin A. Weinstein, Vernon A. Weinstein, Julius L. Weissberg and Louis E. Zaretsky.

WOMEN'S AUXILIARIES AID RELIEF COMMITTEE

The Medical and Surgical Relief Committee of America with headquarters at 420 Lexington Avenue, New York, acknowledges the generous cooperation of the following women's auxiliaries to various county and state medical societies, through whose efforts twenty-two emergency medical field sets, supplies and equipment valued at \$15,000 have been sent out by the national committee:

Georgia State Medical Society
Cook County Medical Society, Illinois
Shreveport Medical Society, Louisiana
Genesee County Medical Society, Michigan
Houghton-Keweenaw-Baraga County Medical Society, Michigan
Jackson County Medical Society, Michigan
Kent County Medical Society, Michigan
Marquette-Alger Medical Society, Michigan
Michigan State Medical Society
Tri-County Medical Society, Michigan
Hennepin City Medical Society, Minnesota
New Hampshire State Medical Association
Bergen County Medical Society, New Jersey
Middlesex County Medical Society, New Jersey
North Carolina State Medical Association
Wake County Medical Society, North Carolina
Belmont County Medical Society, Ohio
Mohawg County Medical Society, Ohio
Ohio State Medical Association
Bradford County Medical Society, Pennsylvania
Cambria County Medical Society, Pennsylvania
Clinton County Medical Society, Pennsylvania
Lehigh County Medical Society, Pennsylvania
Luzerne County Medical Society, Pennsylvania
Mercer County Medical Society, Pennsylvania
Montour County Medical Society, Pennsylvania
Ellis County Medical Society, Texas
Richmond County Medical Society, Virginia
West Virginia State Medical Association

CONSERVATION OF MEDICAL AND SURGICAL SUPPLIES

The Office of Civilian Defense, Washington, D. C., August 21, issued Medical Division Memorandum No. 16 which was forwarded through the state chiefs of emergency medical service to local chiefs and to hospitals and state and local medical societies. The statement emphasized that the medical profession and the hospitals of the nation will shortly be obliged to depend on dealers' stocks of medical and hospital supplies if they are to maintain their present level of efficiency. The continued shortage of raw materials makes it evident that even the armed forces may have difficulty in securing their requirements. Stocks on the shelves of the dealers of this nation constitute the only reserve of medical and hospital equipment which may be available in the near future to meet civilian needs. The hoarding and dead storage of equipment and supplies for a possible emergency should therefore be discouraged. Any unexpected emergency could be met by our present civilian medical and hospital resources. Continued disaster could be met only by the utilization of military stores which would be made available if there should be urgent need.

Any surplus or obsolete equipment now in the possession of physicians and hospitals ought not to be dispersed at this time because of the difficulty of replacement and the possibility that it may be needed for the establishment of emergency base hospitals.

WAR CASUALTIES

The Office of War Information announced on July 21, according to the Associated Press, that the U S armed forces had suffered since the start of the war 44,143 casualties, including 4,801 dead, 3,218 wounded and 36,124 missing. The total included those of the Army, Navy, Marine Corps, Coast Guard and the Philippine scouts, but not the casualties of the Philippine Commonwealth Army. Since the bulk of the army casualties fall in the category of missing, most of whom were at Bataan and Corregidor and in Java, they are believed to be prisoners of war, although no definite report as to their status has been received from the International Red Cross. Those reported killed comprised 902 in the Army, 3,420 in the Navy and 479 in the Philippine scouts. The wounded comprised 1,413 in the Army, 1,051 in the Navy and 754 in the Philippine scouts. Those reported missing comprised 17,452 in the Army, 7,672 in the Navy and 11,000 in the Philippine scouts.

CHICAGO GROUP ON ACTIVE DUTY

Thirty-seven physicians, mostly at present or formerly associated with St Luke's Hospital, Chicago, were commissioned in the United States Army Medical Corps in July and ordered to report for duty at an air corps medical unit in a western state. The following are members of this group: Majors James W Clark, Percy J Ross, Fred E Ball, Claude N Lambert, John I Brewer and Robert E Williams, Capts Willis G Diffenbaugh, John H Pribble, Howard W Merideth, Chester Coggeshall, Robert G McMillan, William L Waskow, Leslie R Grams, George A Ingrish and Paul H Dube, Lieuts LeRoy E Walter, Claude R Snead, Frank W Jones, Joseph A Davis, William Burgett Smith, Clarence Kristiansen, John B Case, Carl H McLauthlin, John T Parker, Don J Hunter, Frank R Gondek, Lawrence De Renne, Robert C Lawson, Ryland A Buckner, Thomas G Hobbs, Hosmer T Merrell, Stephen C Scott and Richard Oliver. Lieuts J S Clark Jr, Francis S North and Brendan P Phibbs were ordered to report to Carlisle Barracks, Carlisle, Pa, for training before joining their units elsewhere.

EMERGENCY MEDICAL SERVICE IN WAR
DEPARTMENT PLANTS

The Office of Civilian Defense has notified its regional medical officers that General Somervell, commanding the army services of supply, has ordered all plants owned by the War Department, as well as civilian plants engaged in production of war material, to plan with local chiefs of the Civilian Defense Emergency Medical Service for the use of available emergency medical facilities. General Somervell also ordered plant protection inspectors to make sure such plans have been formulated. The Office of Civilian Defense has also announced that the Navy is sending out with its official approval OCD recommendations regarding coordinated plans by industrial plants to use the protection facilities of the Emergency Medical Service in the same manner.

The OCD memorandum also outlined plans for all factories. Industrial plants are expected to provide medical services and first aid equipment within the plant, but, in event of enemy action, plant physicians, nurses and first aid detachments may be unable to care for all the seriously injured. "It is considered essential, therefore," the OCD said, "that protection of personnel in the plant be coordinated with the local Emergency Medical Service, so that plant facilities may be supplemented by those of the OCD organizations in case of need."

YOUNGSTOWN'S AMBULANCE POOL

For emergency purposes the ambulances in Youngstown, Ohio, have been pooled and assigned to one of two "identification centers," where they will go at the first sound of the alert and await orders from the control center in the city. The ambulances will be supplied by the undertakers under the Mahoning County civilian defense plan. All drivers and assistants assigned have been trained in first aid.

YALE HOSPITAL UNIT MOBILIZED

The Yale University Medical School Hospital Unit was mobilized on July 15 for war duty as U S Army General Hospital No 39, the personnel of which will comprise some fifty physicians, seven dentists and one hundred and three nurses and civilian specialists. The Yale Unit in the first world war (Mobile Hospital No 39) is said to have been the first American hospital unit to land in France and among other places served during the St Mihiel offensive. The present unit will undergo a period of training and then is expected to go on foreign service. Dr James C Fox Jr, clinical professor of neurology at Yale, who has been acting director of the unit now becomes chief of the medical service with rank of lieutenant colonel. Lieut Col Ashley W Oughterson, associate professor of surgery, will be chief of the surgical service. According to the *New York Times* the following members are from the greater New Haven area except where noted.

LARGEST CLASS GRADUATES AT
CARLISLE BARRACKS

More than eight hundred officers of the medical department, representing the largest class in the history of the Medical Field Service School at Carlisle Barracks, Pa, graduated from a field training course July 31 and left after the ceremonies to join their respective units. The class was addressed by Major Gen James C Magee, Surgeon General of the Army, who was introduced by Brig Gen Addison D Davis, commandant. A brief history of the school was given at this time by Col Albert S Dabney, assistant commandant. The officers graduating were chiefly first lieutenants who had recently completed their internships. The subjects taught included military sanitation, military art, field medicine, administration and logistics.

OAKLAND WILL REIMBURSE HOSPITALS

The city of Oakland, Calif, and the local hospitals have entered into a contract, according to *Modern Hospital* of August 1942, whereby the city agrees to pay the hospitals for the care of civilian air casualties the difference between \$375 a day, which the federal government will pay under the Office of Civilian Defense program, and the actual cost of the service rendered, which, however, cannot exceed the charge regularly made for industrial accident cases. This contract, it is said, is made in consideration of the hospital's agreement to maintain emergency medical services for the care of civilian air casualties.

DUKE HOSPITAL UNIT GOES ON ACTIVE DUTY

The officer personnel of the U S Army Hospital No 65, which is composed largely of members of the staff of Duke Hospital Durham N C former staff members and alumni of Duke University School of Medicine departed on July 15 for an unannounced station for active service. The Duke Medical Unit comprising fifty-eight physicians dentists and administrative officers has been in process of organization for more than a year and although forty-seven of its staff members are said to be North Carolinians some who joined the unit have been practicing in many parts of the country. The members were given a farewell party at the Hope Valley Country Club at which time a United States flag was presented to the unit. Lieut Col Elbert L Persons will be chief of the medical service and Lieut Col Clarence E Gardner chief of the surgical service. The chief nurse will be Miss Elizabeth White, assistant superintendent of nurses at Duke Hospital. According to the Durham (N C) *Morning Herald* the roster of officers is as follows:

MEDICAL OFFICERS FOR NEW DIVISIONS

At the Medical Field Service School Carlisle Barracks Pa, a class of medical officers and medical administrative officers were awarded diplomas following a special training course for particular assignments in medical battalions of several triangular infantry divisions which are being activated. This class received its special training at the same time that classes were being conducted at other army service schools to train officers of other branches of the army similarly. The graduates who came from twenty-seven different states left immediately after graduation to take their positions in the new units being organized. Another class to take the course arrived at Carlisle Barracks the following day.

THE ST LOUIS ARMY MEDICAL DEPOT

The addition of several stories to the Medical Depot at St Louis, which is expected to be completed this month will make this building the largest structure in the city a position which was formerly held by a bottling plant of the Anheuser-Busch Company, which had 25 acres of floor space under one roof. The building which has been remodeled was purchased by the War Department about a year ago. The director of the depot at the time of this report was Col Royal K Stacey.

FLAG PRESENTED TO NEW OREGON UNIT

At a ceremony at the University of Oregon School of Medicine the flag of the University of Oregon Medical School Unit (Base Hospital No 46), which served in France in the first world war was presented to the new University of Oregon Medical School General Hospital Unit, which then left for a period of training in Kansas. The flag of the old unit is said to have been the first U S emblem to enter Cherbourg in the first world war and after the war was returned to the medical school for safe keeping through the intervening years. At the ceremony the flag was presented to the new hospital unit by Dr Thomas M Joyce who commanded Base Hospital No 46 in 1918 the nurses' flag of the unit was presented by Grace Phelps who was chief nurse of the old base hospital and recently retired as superintendent of nurses at the Doernbecher Hospital. The staff of the new unit comprises some sixty physicians and one hundred nurses. Others participating in the ceremony were Donald M Erb president of the University of Oregon Chancellor Frederick M Hunter Associate Dean David W F Baird Ralf Couch administrator of the university hospitals and Elmer Thomson head of the department of nursing.

FEDERAL AID FOR MEDICAL STUDENTS PURSUING ACCELERATED COURSES

Regulations have now been issued by the U S Office of Education for the distribution of the five million dollars recently made available by Congress to aid financially students participating in accelerated programs in certain degree granting colleges including medical colleges (*Federal Register* 7 6747 [Aug. 26] 1942). The Office of Education has also issued a mimeographed memorandum containing a series of questions and answers as a guide to colleges and universities desiring to participate in the loan program. Each institution having an approved accelerated program desiring loans for any of its students must submit to the Commissioner of Education on SWI Form 1 its plan of accelerated program the number of students pursuing the course and an estimate of the number of such students needing loans together with the total loan fund allotment required to meet such estimated needs. Copies of all regulations forms and other material relating to this loan program may be secured from the U S Office of Education Washington D C.

CHEMICAL WARFARE DEMONSTRATIONS AT BUFFALO

The War Department's Civilian Protection School, the Health Preparedness Commission of the State War Council and the Buffalo Emergency Medical Service arranged demonstrations on August 7 in which sixty-two physicians obtained practical experience in chemical warfare following a brief lecture by Major Theodore F Odland U S Army. Shells of various types of warfare gases were detonated the physicians were taught how to apply gas masks and then they entered a tear gas chamber. Major Odland was assisted in these demonstrations by Dr Roy M Siedeman of Rochester district medical officer of the Health Preparedness Commission, and by Mayor Bourke of the New York State Health Preparedness Commission.

SHORT COURSES IN LITTLE ROCK ON POISON GAS

The University of Arkansas School of Medicine, Little Rock in cooperation with the state board of health and the Office of Civilian Defense will begin short courses of about a week in a statewide program to instruct physicians, nurses and others in methods of defense against poison gas. The instructors will be Dr Fred William Harris assistant professor of medicine, and Dr Randolph Smith professor of surgery, who recently attended a chemical warfare course sponsored by the Office of Civilian Defense at the University of Cincinnati, other members of the faculty of medicine will assist in the instruction.

ENLISTED MEN COMMISSIONED TO RELIEVE PHYSICIANS FROM ADMINISTRATIVE WORK

A class of several hundred enlisted men chosen for their ability, education and faithful performance of duty completed an intensive training course at the Medical Field Service School Carlisle Barracks, August 25, and were commissioned second lieutenants in the Medical Administrative Corps. Other classes had previously graduated and others are now undergoing training. The new officers will take over the administrative duties in medical units and thereby release medical officers for professional work. Forty-one states and the District of Columbia were represented in the class, and the new officers represented thirty-four types of civilian occupations. The commissions were presented by Brig Gen Addison D Davis, commandant of the school, and the oath of office was administered by Major Thomas E Hester, adjutant of the Army Medical Center at Washington, D C, one of the senior officers of the Medical Administrative Corps. Major Gen James C Magee, Surgeon General of the Army, sent a special message of congratulation.

THREE DAY COURSE IN CHEMICAL WARFARE

Seventy doctors from the New England states completed a three day course in chemical warfare August 9 at a school in Boston, where they learned the technic of using gas masks in actual experience with war gases. The students mastered the technic of removing the mask from the container and putting it on in the recognized normal time of eleven seconds. At one of the fire department stations they entered a chamber filled with tear gas and then observed a demonstration at the Huntington Memorial Hospital of how gas victims are decontaminated.

NAMES FOR NEW ARMY HOSPITALS

An army general hospital located in Iowa will be called the Schick General Hospital, in honor of Dr William R Schick Jr of Chicago, who is said to have been the first U S Army flight surgeon to lose his life in this war. Dr Schick was killed at Pearl Harbor. An army hospital in Tennessee has been named the Kennedy General Hospital, in honor of the late Brig Gen James M Kennedy, U S Army Medical Corps, who during the first world war was surgeon for the New York port of embarkation and later was in command of the Walter Reed General Hospital.

DR LOYAL DAVIS ON DUTY IN SURGEON GENERAL'S OFFICE

Dr Loyal Davis, head of the surgical department of Northwestern University Medical School, Chicago, and editor of *Surgery, Gynecology and Obstetrics* has been commissioned a lieutenant colonel in the U S Army Medical Department and assigned to duty as consultant in neurosurgery in the Surgeon General's Office, Washington, D C. Dr Davis served in the first world war and from 1922 to 1924 was associated with the late Dr Harvey Cushing of Boston. He then came to Chicago as associate professor of surgery at Northwestern and in 1932 became head of the department of surgery.

NINE DAY COURSE IN DEFENSE INSTRUCTION

Sixty-six civilian defense leaders from southern California and Arizona on August 3 began a nine day course of defense instruction at Occidental College, Los Angeles. The course was under the supervision of the Chemical Warfare Service and included first aid, war gases, explosives, gas decontamination, air raid warning systems and other defense measures. Similar courses for educational executives and others in essential defense industries were to follow.

TULANE MEDICAL UNIT ACTIVATED

Tulane University, New Orleans, tendered a farewell banquet to the members of its medical unit at the Jung Hotel July 9 prior to activation of the unit for service with the armed forces. The unit Army General Hospital No 24 was organized more than a year ago under the supervision of Lieut Col Muns Gage, who will be chief of the surgical service. Lieut Col Roy Hope Turner will be chief of the medical service. On this occasion the colors were presented to Col Clifford Roy, commander of the unit, on behalf of the board of administrators and the faculty of the university. The principal speaker was Dr Rudolph Matas, who organized Base Hospital No 24 for service in the first world war. Dr Matas reviewed the history of the former Tulane Medical Unit and expressed a wish that its traditions be carried on by the present group. Other speakers were Dr John H Musser, toastmaster, Dr King Rand, who served with Base Hospital No 24 and Drs Gage and Turner. According to the New Orleans *Times-Picayune* the other members of the staff are as follows:

MAJORS

John J Archward	James B McLester
Henry J Bayon Jr	John M Miles

GENERAL KELSER RECEIVES AWARD

Brig Gen Raymond A Kelser, chief of the Army Veterinary Corps, has been awarded the twelfth International Veterinary Congress award for distinguished service to veterinary science in the fight against livestock diseases. According to the *Army and Navy Journal* the award was made at the seventy-ninth annual meeting of the American Veterinary Association in Chicago, August 24. General Kelser's long and distinguished career in the Veterinary Corps dates back to World War I.

CONVERT CARRIAGE HOUSE INTO HOSPITAL

The carriage house at the wooded estate of Mrs Charles S Cutting in Gladstone N J, has been converted into an emergency hospital with a capacity for 250 patients. Already some of the beds are occupied by overflow patients from the Lakes Medical Center and other hospitals in the vicinity. According to the Chicago *Sun* of August 6 the hospital is among Mr Cutting's contributions to home defense.

PERSONAL

Dr Ralph A Kordenat of Chicago has been appointed vice medical chairman of Cook County for the Procurement and Assignment Service. Col Frank W Weed, Medical Corps, U S Army, who has been commanding officer of the Letterman General Hospital, San Francisco, has been nominated by the President for promotion to the rank of brigadier general.

The Woman's Auxiliary to the state medical association will open its program on September 21 Dr Henry R Carstens, Detroit, president of the state medical association, resigned on July 15 to go on active duty in the armed forces of the United States Col George F Lull, M C, U S Army, Washington, D C, will deliver the Biddle Oration, Wednesday evening, on "Resume of Military Medical Personnel Problems in the Army" Lieut Col Samuel F Seeley, M C, U S Army, Washington, D C, will be the guest speaker at the Secretaries Conference on Wednesday

NEW JERSEY

Twelve Fined for Violating Paralysis Quarantine—Twelve residents of Seth Boyden Court, a federal housing project in Newark, were fined from \$5 to \$50 by Chief of Police Magistrate Ernest F. Masini, August 31, for violating the city health department regulations by removing children from their apartments on the property while the place was under quarantine for infantile paralysis. According to the *New York Times*, the complaints were signed by Dr. Charles V. Craster, health officer of Newark. In fining three of the offenders \$50, Judge Masini said that the differences in the penalties were based on the manner of removing children and their control with regard to public health laws. All the children involved have since been returned to the quarantined premises, it was stated. The seventh case of infantile paralysis at the project was reported on August 31 by Dr. Craster. Since July 1 there have been 17 cases in the city, 1 resulting fatally.

Sentence Physician Accused of Altering Fingerprints—Dr. Leopold W. A. Brandenburg, Union City, was given the maximum sentence of three years' imprisonment on August 20 for aiding, giving comfort and concealing a fugitive from prosecution. According to the *Yonkers Herald-Statesman*, Dr. Brandenburg, accused of performing an operation in an attempt to change the fingerprints of Robert (Rosecoe) James Pitts, was convicted on August 14 by a jury of eight men and four women. It was also reported that at his trial the physician acknowledged that in May 1941 he cut away the skin of the finger tips of Pitts, a convicted burglar sought by North Carolina police for questioning in connection with two burglaries, and bound his hands to his chest to form new fingerprints. He testified, however, that he did not know then that Pitts now serving a sixteen to twenty year term for burglary in North Carolina, was an object of a police search. Pitts, who was brought from the North Carolina Prison to testify against Dr. Brandenburg, had served terms at Alcatraz and Atlanta prisons, it was stated.

NEW MEXICO

State Medical Election—Dr. Joseph E. J. Harris, Albuquerque, was chosen president-elect of the New Mexico Medical Society at its annual meeting in June and Dr. Wallace P. Martin, Clovis, was inducted into the presidency. Dr. Leo B. Cohenour, Albuquerque, was reelected secretary. The 1943 session will be held at Albuquerque, May 19-21.

NEW YORK

District Meeting—The thirty-sixth annual meeting of the Sixth District Branch of the Medical Society of the State of New York will be held in Endicott, September 16. At the morning session Dr. Ernst P. Boas, New York, will discuss "Treatment of the Aged" and Leonard A. Maynard, Ph.D., Ithaca, "Nutrition Survey of Recent Findings and Discussion of General Problems." A symposium on medical indemnity will be conducted in the afternoon by Drs. Frederick M. Miller Jr., Utica, Harvey P. Hoffman, Buffalo, and Frederic E. Elliott, Brooklyn.

General Electric Builds High Voltage Machine—A machine is under construction at the General Electric Research Laboratory, Schenectady, which will speed electrons to energies of 100,000,000 volts and which will produce x-rays of the same power. The machine, which will be housed in a special building, is called an "induction electron accelerator." Ernest E. Charlton, Ph.D., head of the x-ray section of the General Electric Laboratory, and W. F. Westendorp have been responsible for the design and construction of the new accelerator. Its principal part will be a huge electromagnet weighing 125 tons.

Outbreak of Gastroenteritis—An outbreak of gastroenteritis occurred during the week of June 29 among residents of two neighboring upstate villages and one death occurred among the 130 persons involved. According to *Health News*, both villages used untreated water from a common source and distribution system privately owned and operated. Following a break in the water main, bacteria of the coliform group were found in water samples collected. Inquiry at the first residence along the water line as it enters the village disclosed that the water pressure was not constant and at times was rather low. It was also found that the septic tank at the second residence overflowed into a small marshy area to the rear of the house. In nearly all the homes along the water main one or more persons had been affected.

New York City

Hospital News—The New York Hospital has opened a pavilion of twenty-nine beds for the study and treatment of neurologic cases, both medical and surgical. Dr. Harold G. Wolff is the neurologist in charge, and neurosurgery is under the direction of Dr. Bronson S. Ray.

Fund in Memory of Dr. Norris—The New York Academy of Medicine will receive about \$170,796 from the residuary estate of Miss Fanny Norris to establish a fund in memory of her brother, the late Dr. Charles Norris, formerly chief medical examiner of the city, who died Sept. 11, 1935.

Charles Hendee Smith Retires—On September 1 Dr. Charles Hendee Smith retired as professor of pediatrics at the New York University College of Medicine. Dr. Smith was a member of the staff of Columbia University College of Physicians and Surgeons from 1903 to 1930, when he went to New York College.

Commander Wells Chosen President-Elect of the American Dental Association—Comdr. C. Raymond Wells, DDS, Brooklyn, chief dental officer, medical division, Selective Service System, Washington, D. C., was chosen president-elect of the American Dental Association at the meeting of its house of delegates in St. Louis, August 26. Dr. Wells graduated at Northwestern University Dental School, Chicago, in 1918.

Director of Division of Handicapped Children—Dr. George S. Frauenberger, director of clinics of the Children's Hospital of Philadelphia, has been appointed chief of the division of physically handicapped children in the bureau of child hygiene of the department of health. He succeeds Dr. Lymon C. Duryea, who is serving with the armed forces. Dr. Frauenberger graduated at the University of Michigan Medical School, Ann Arbor, in 1933. The division of physically handicapped children was first established in 1940 as the division of crippled children. It has carried the current name since July 1, when the Cardiac Classification Service was included. Its headquarters are located at the lower east side health center, 341 East Twenty-Fifth Street, Manhattan. The funds for financing the work have been provided by the city department of health from appropriations secured under the Social Security Act through the children's bureau of the United States Department of Labor.

NORTH CAROLINA

University News—William A. Wolff, Ph.D., has been named as associate professor of biochemistry in charge of chemical pathology at the Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, effective July 1, and Dr. Robert B. Lawson, Chapel Hill, has been named assistant professor of pediatrics. The establishment of the Nathalie Gray Bernard Lectureship was announced at a meeting of the student body on June 29. Voluntary contributions will make up the fund, which will finance the visit each year of a lecturer to the school.

Personal—Dr. Julian W. Ashby has resigned as superintendent of the State Hospital, Raleigh, having recently become eligible for retirement under the state system. Dr. John F. Owen, Raleigh, formerly assistant, has been named acting superintendent. Dr. Frank K. Harder, assistant health commissioner of Cincinnati, has been appointed head of the Greensboro Health Department, effective August 3. Dr. Walter E. Wilkins, Raleigh, director of the division of school health service for the state board of health, has been made consultant in nutrition to the Office of Defense Health and Welfare Services in Washington. Dr. Roy H. Long, assistant superintendent and for more than twenty years a member of the staff of the state hospital at Morganton, resigned, August 1, on account of ill health.

OKLAHOMA

Physicians to Be Paid for Examinations—Beginning on August 15, physicians will be paid a fee by the state public welfare commission for the examination of applicants seeking assistance from the aid to dependent children's fund when such applicants are applying for reason of physical or mental incapacity, according to the state medical journal. The program calls for the payment of a \$3 fee for original examinations and \$2 for subsequent reexaminations. Laboratory work will also be paid for when requested by the medical advisory committee. Applicants will use their family physicians or one of their own choice. The recommendations for this plan came from the medical advisory committee and were adopted by the commission to secure more complete examinations of the appli-

cants by physicians whereby, in return, a more definite decision could be obtained as to whether the applicant was entitled to assistance. It is believed that the new examination form and the payment of an examination fee will save thousands of dollars for the taxpayers of the state. Members of the medical advisory committee are Drs Charles R Rountree, Oklahoma City, John Walker Morledge, Oklahoma City, Alfred R Sugg, Ada, C Gallagher, Oklahoma City, Robert M Shepard, Tulsa, and Moorman P Prosser, Norman.

PENNSYLVANIA

State Medical Meeting in Pittsburgh—The ninety-second annual session of the Medical Society of the State of Pennsylvania will be held at the Hotel William Penn, Pittsburgh, October 5-8 under the presidency of Dr Lewis T Buckman, Wilkes-Barre. The program has been divided into three morning general assemblies consisting of panel discussions. Wednesday's meeting will be devoted to discussions of coma and shock and Thursdays to intravenous therapy. One hundred and seven speakers will participate in eight scientific sessions covering the specialties. Among the out of state speakers will be

- Col. George R Callender M C U S Army, Washington, D C Wound Ballistics
- Dr Alan C Woods Baltimore Influence of Sensitivity and Immunity on Ocular Tuberculosis
- Dr Charles B Higgins Chicago Endocrine Relationships in Carcinoma of the Prostate
- Dr Lloyd D Felton Washington D C Possibility of the Prophylaxis of Pneumonia
- Dr Henry C Marble Boston Treatment of the Injured Hand
- Dr Philip Levine Newark N J Erythroblastosis in Reference to Abortions and Neonatal Deaths
- Dr L Emmett Holt Jr Baltimore The B Vitamins and Their Significance for the Pediatricians
- Dr C Stewart Nash Rochester N Y Functional Diseases of the Nose
- Dr John H Foulger Wilmington Del Important Factors in Industrial Preventive Medicine
- Dr Thomas E Jones Cleveland Diagnosis and Surgical Aspects of Carcinoma of the Colon
- Dr Joe V Meigs Boston Ovarian Tumors
- Dr William E Ladd Boston The Time of Choice and Operation of Choice in Elective Surgery of Infancy and Childhood
- Dr Adrien H Verbrugghen Chicago Coma and Shock
- Dr Russell L Haden Cleveland Intravenous Therapy
- Dr Harry M Robinson Baltimore Resumption of Antisiphilic Treatment After Postarsphenamine Reactions

Philadelphia

Committee Named to Conserve Physicians' Activities—A coordinating committee has been formed of representatives of the College of Physicians of Philadelphia and the Philadelphia County Medical Society to correlate the scientific activities of both organizations. According to *Philadelphia Medicine*, it is hoped that this idea may be followed by other organizations in order that the number of medical meetings may be reduced and the efforts of the physicians remaining in civilian activity extended where they will do the greatest amount of good.

VIRGINIA

Dr Royster Retires as Professor—Dr Lawrence T Royster has resigned as head of the department of pediatrics at the University of Virginia Department of Medicine, Charlottesville. Dr Royster graduated at the university in 1897 and has been in charge of the department of pediatrics since 1923. He was secretary of the section on pediatrics of the American Medical Association from 1910 to 1911 and chairman, 1914-1915.

WEST VIRGINIA

Resolution About Contraceptive Information—The West Virginia State Medical Association adopted a resolution on July 14 which favored the dissemination of birth control information by physicians. The resolution reads as follows:

WHEREAS The maternal death rate in the state of West Virginia has been and still is one of the highest in the United States; therefore, be it Resolved That the physicians of the state of West Virginia and the state department of health of the state of West Virginia be requested to impart the necessary contraceptive information to those women whose health is such that they should not bear children and to those mothers whose health has been impaired by excessive childbirth.

Auxiliary Compiles Book on Past Presidents—The Woman's Auxiliary to the West Virginia State Medical Association published in July a book entitled "Past Presidents of the West Virginia State Medical Association 1867-1942." The project was begun four years ago. The book opens with a chapter on the establishment in 1867 of the state medical society and a review of its history and contains pictures and backgrounds. Fifteen of the past presidents were charter members of the state medical association. There are twenty-three living past presidents of the association.

GENERAL

Directory of Industrial Hygiene Personnel—A directory has been issued by the division of industrial hygiene, National Institute of Health, U S Public Health Service, Bethesda, Md, showing professional personnel of state and local hygiene units. The directory gives the address, name and title of industrial physicians, engineers, chemists, bacteriologists, inspectors and nurses employed in the several states.

Fire Prevention Week—The President has issued a proclamation setting aside the week of October 4-10 as fire prevention week. All agencies throughout the country are asked to cooperate in attacking and eliminating fire hazards in an effort to reduce loss of life and property from blaze and smoke in every state in the union. The Office of Civilian Defense has been directed to initiate programs for emphasizing the importance of attaining these objectives.

Automobile Identification Plates for Use in Blackouts—The Medical and Surgical Relief Committee of America announces new automobile identification plates for physicians during blackouts. They are made of washable plastic board with the letters M D conspicuously imprinted in white against a black background. The committee's emblem, a modified caduceus, is also imprinted on the plate. The price is \$1.50. The new plates may be obtained from the Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York. Any small profit accruing from the sales of these plates will be used to purchase instruments and medical supplies for areas which cannot obtain them otherwise.

Association of Science Writers—Watson Davis, director, Science Service, Washington, D C, was chosen president of the National Association of Science Writers at its recent annual meeting in Atlantic City and Stephen McDonough, science writer, Associated Press, Washington, D C, was reelected secretary-treasurer. Rennie Taylor, Associated Press, San Francisco, James Leary, Chicago *Daily News*, Chicago, and Jay Edgerton, Minneapolis *Journal*, Minneapolis, were elected to active membership. Sidney S Negus, PhD, head of the department of chemistry, Medical College of Virginia, Richmond, was named to honorary membership, and Lawrence Salter of the American Medical Association, Chicago, to associate membership. On August 19 announcement was made of the election to honorary membership of Hon Henry A Wallace, vice president of the United States in recognition of his many contributions to the popularization of science and particularly for his research contributions in the field of genetics.

Motion Picture on Immunization Available—The professional department of Lederle Laboratories, Inc, 30 Rockefeller Plaza, New York, announces the release of a film "Immunization Against Infectious Diseases," prepared by the department of pediatrics and communicable diseases, University of Michigan Medical School with the approval of the American Academy of Pediatrics and its Committee on Immunization Procedures. The picture, supervised by Drs Charles F McKhann and Harry A Towsey, Ann Arbor, is in technicolor and shows patients with typical diagnostic signs, maps showing geographic distribution and procedures outlining protection against diphtheria, scarlet fever, tetanus, pertussis, typhoid fever, cholera, plague, smallpox, rabies, encephalomyelitis, yellow fever, Rocky Mountain spotted fever and typhus fever, and measles also the proper time of immunization against these diseases. The picture is available for bookings without charge to medical societies, public health departments, hospitals and medical and nursing schools.

Seminar in Legal Medicine—A medicolegal conference under the auspices of the Massachusetts Medico-Legal Society and the department of legal medicine Harvard Medical School, Boston, will be held at the Mallory Institute of Pathology, Boston City Hospital, September 30. The conference will be open to physicians, lawyers and police and subjects will include the medical examiner and the public health department establishment of time of death, examination of burned, mutilated and putrefied bodies, interpretation of laboratory reports of the carbon monoxide and alcohol content of postmortem materials, examination of bodies recovered from water hit and run accidents, collection and preservation of material for toxicologic analysis and legal considerations incident to the performance of autopsies. There will also be a demonstration of the medicolegal autopsy. Dr William H Watters, Boston, who will open the conference, is chairman of the committee. This conference will precede a seminar in legal medicine under the auspices of Courses for Graduates, Harvard Medical School, which will consist in studies of many postmortem investigations made from the medicolegal standpoint and the various procedures associated with possible crime detection.

CANADA

Personal—Dr James B Collip, professor and head of the department of biochemistry, McGill University Faculty of Medicine, Montreal, Que., was elected president of the Royal Society of Canada on May 30—Dr George Dana Porter, first director of student health service at the University of Toronto, was presented with a plaque at a dinner given in his honor, May 21, in recognition of his many years' service to the university. Dr Porter was director of the student health service from the time of its inception in 1921 to his retirement in 1941. He was also recently elected an honorary life member of the Canadian Public Health Association.

Special Society Meetings—The Canadian Public Health Association held its thirty-first annual meeting at the Royal York Hotel, Toronto, June 1-3, in conjoint session with the twenty-eighth annual conference of the Ontario Health Officers Association. Henry F Vaughan, Dr P H., dean of the School of Public Health of the University of Michigan, Ann Arbor, was the guest speaker at the annual banquet—The forty-second annual meeting of the Canadian Tuberculosis Association was held in conjunction with the Ontario Laennec Society at the Royal Connaught Hotel, Hamilton June 5-6. At the annual dinner Dr Norman S Shenstone, Toronto, discussed "Pneumectomy."

LATIN AMERICA

School for Handicapped Children—A special school for children whose mental or physical handicaps prevent their education with normal children is to be established in Panama under a presidential decree promulgated on May 15 through the Ministry of Education. The decree also provides for the formation of a committee for child study, which will function under the technical department of the ministry of education. According to the *Child* the committee is to be composed of "an educator with a university degree in psychiatry, a psychiatrist, an educator with experience in the teaching of mentally deficient children and a social worker." It is to determine the number of mentally and physically handicapped children in Panama and to develop special courses of study for the school for handicapped children which will best assure the assimilation of these children in the cultural and economic life of the nation.

FOREIGN

Personal—Dr Eugene Chan, Chengtu, has been appointed visiting professor of ophthalmology at the National College of Medicine of Shanghai China. Dr Chan, who was once a member of the Wilmer Ophthalmological Institute of Johns Hopkins University, Baltimore, has during the last few years held the chair in ophthalmology at the West China Union University School of Medicine and has been head of the department of ophthalmology of the Chengtu Eye, Ear, Nose and Throat Hospital.

Institute of Social Medicine Endowed—The Nuffield Provincial Hospitals Trust will devote £10,000 a year for ten years to the creation at the University of Oxford of a university professorship of social medicine and the foundation of an institute in which the professor will work according to *Science*. The purposes of the institute are:

To investigate the influence of social, genetic, environmental and domestic factors on the incidence of human disease and disability.

To seek and promote measures other than those usually employed in the practice of remedial medicine for the protection of the individual and of the community against such forces as interfere with the full development and maintenance of man's mental and physical capacity.

If required by the university to do so to make provision in the institute for the instruction in social medicine of students and practitioners of medicine approved by the board of the faculty of medicine in the University of Oxford.

The entire project has been carried out with the approval of Lord Nuffield, who six years ago devoted two million pounds to the endowment of medical research in the University of Oxford. In December 1939 he endowed the Nuffield Provincial Hospitals Trust of which William M Goodenough, chairman of the trust connected with medical endowment at Oxford University, is the chairman. This trust is empowered to spend money on a wide range of purposes which can be of benefit to the hospital services.

CORRECTION

St Luke's Hospital Approved for Surgical Residencies—In the Educational Number of THE JOURNAL August 15 page 1341, St Luke's Hospital 421 West 113th Street New York City should have been listed as approved for residencies in surgery. Dr William F MacFee is chief of the Surgical Service. Inpatients treated 3,450 outpatient visits 27,236 deaths 102, autopsies 52, number of residents 2, assistant residents 8.

SPECIAL NEWS

(THIS NEWS WAS ASSEMBLED ESPECIALLY FOR USE IN THE JOURNAL)

Health Under Hitler—According to the *Scenska Dagbladet* Stockholm, of July 6 thousands of wounded Germans are being transported to Norway and the Norwegians turned out of hospitals to make room for them. Practically every hospital in the interior is requisitioned for the Germans and the Norwegian patients are sent to school buildings which have been prepared for them. It was estimated that the transfer of patients would take until the end of July during which period the hospitals will hardly be able to function. The press announces that civilian sick cannot be accepted for hospital treatment before the end of July since the German defense forces have requisitioned the hospitals. According to the *Rykan Dagblad* of July 1, after the German wehrmacht's requisitioning of Tolmark County Hospital it was decided that the patients must move to Soere Agricultural School Ulofoss.

The *Neues Wiener Tagblatt* of July 4 describes the journey of a Danube steamer from Vienna to Durnstein with a party of wounded soldiers. The boat which had been hired by the Wehrmachtskommandantur Wien Verwundetentraining for July and August, will make the trip three times a week carrying chiefly seriously wounded men. After two hours at Durnstein the boat returns to Vienna. The organization for the care of the wounded in which Lieutenant General Stumpf takes particular interest, deals with 100,000 wounded soldiers a month. The first lot of 500 soldiers was accompanied by doctors, nurses, a band, a quartet and singers. There were soldiers from all fronts, "from Lapland to Africa."

Otto Mattson an expert of the Lund Anatomic Institute stated in an interview, according to the *Social Demokraten* of August 6 that certain scientific instruments, such as binocular microscopes, barometers, thermometers and double polished glass are unobtainable in Germany. High class cameras are difficult to obtain. It is not easy to obtain ordinary glass, which however, is still being manufactured.

According to *Novo Vreme*, Belgrade, of June 18 owing to the shortage of pharmaceutical products and to prevent speculation the sales of these articles are controlled. Castor oil, iodine, petrolatum and quinine are obtainable in future only on a doctor's prescription.

Children's stockings for months have been unobtainable in Finland, according to *Helsingin Sanomat* of August 4 and shoes are seldom seen. It is said to be impossible to find even the most modest clothes for children although adults can still buy clothes.

According to the *National Zeitung* Berne July 16 reports are that German soldiers fighting in Russia are now being smeared with a preparation to protect them against lice. The preventive is the outcome of experiments made by Hitler's doctor Professor Morell who found that lice placed on horses fell off dead. He discovered that the reason was horse perspiration. The anti-lice mixture which is also said to possess frost protective qualities has reduced the number of cases of typhus among the German troops, the paper adds.

According to the *Deutsche Wissenschaft, Erziehung und Vollbildung* of June 20 the minister of the interior has advised all volksgenossen who for professional or other reasons go on a visit to occupied countries, the government general or foreign countries, to have themselves vaccinated against typhus and paratyphus. Those who are going to visit any of the occupied eastern areas or the government general are advised also to be vaccinated against spotted typhus. The vaccine is obtainable from the Robert Koch Institute and from the Behring factories in Marburg a d Lahn.

According to the Brussels radio of August 1, the Ministry of Economic Affairs warned against the danger of gas poisoning since the quality of gas for lighting has deteriorated and contains a higher amount of 'coal oxide'. It is more necessary than ever the announcer warned to be sure that no gas escapes anywhere.

Italia Germana Vittoria is the name of the twenty-second child recently born to an Italian woman aged 46 who thus became the woman with the most children in Italy according to the Berlin correspondent of the *Scenska Dagbladet* of August 1. According to the *Nieuw Rotterdamse Courant* of May 18 at the 'Deutsche Haus' at Rotterdam 44 mothers of large families were present at the celebration of the German mothers day organized by the South Holland kring or the NSDAP. The meeting was attended by representatives of the state army and party. Oberdienstleiter Schmidt presented military crosses to the mothers.

Hauptsturmführer Emil Petersen of Usseeroed, now employed in an SS hospital in Vienna, recently visited Denmark, where he exhorted the Danish doctors and nurses to go to Germany, where the demand for their service is great, according to *Fæderlandet* of August 3.

The total population of Belgium has fallen from 8,294,674 to 8,257,392 during the year 1941, a drop of 37,282, according to the *Nachrichten für den Aussenhandel* of August 5. There are 23,725 fewer men and 13,557 fewer women than in 1940, there were 98,417 births and 118,670 deaths recorded. The war has accentuated the falling birth rate of recent years. The Walloon provinces are responsible for the decline, as in the Flemish provinces the number of births exceeds the deaths now as before the war. There have been other changes in the population. As a result of immigration and emigration (3,236 people have entered the country, 13,775 have left it) the number of inhabitants decreased by 10,539. This decrease can largely be accounted for by the number of foreign workmen (Poles, Italians, Yugoslavs) who have returned to their country. The four main Flemish provinces lost a total of 12,759 inhabitants during 1941.

According to the *Het Nationale Dagblad*, Utrecht, of June 13, Dr K. Keijer, leader of the medical front, writes as follows concerning the medical care of the nation's health: "Our social medical science has in the past always been divided by competing organizations—by associations such as the White Cross, Green Cross and Yellow Cross, and much money has been wasted. Our health insurance organizations have also been at variance. All these characteristics of a liberal period must be removed. The executive work in the field of public health must be centralized in a service instituted by the government."

The head of the medical service must himself employ the public health officials and dismiss them (after consultation with the medical front) because, in the last resort, he alone is responsible to the leader and the government. Moreover, it is his duty to see to it that our nation is adequately represented in the international field of public health and actively collaborates in any events or measures relating to public health which may be undertaken by other nations, either separately or together.

"The new public health service will apply more to healthy people than to sick ones. An increase of the healthy and valuable section of the population is more important than the maintenance of the ailing ones."

"The physical training of the young lays the foundations of the nation's health. Boys of 18 years of age should be at least 90 per cent fit for military or labor service, instead of 70 per cent unfit as is the case at present."

"Marriages among the young should be encouraged, which makes it all the more important to look after the purity of the race. The heredity of those who wish to marry will be thoroughly examined and taken into consideration before consent is given to marriage. The undesirable mingling of races must come to an end. And, in the first place, marriages with Jews and alien races must be prohibited."

According to DNB of July 11, expectant mothers require a certificate in order to obtain additional food and supplies. This certificate can be issued by any doctor or midwife. To relieve doctors it is urgently requested that women have their pregnancy certificates issued by midwives.

The reich minister of the interior has decreed, according to NDZ of July 6, that compensation will be paid to health resorts, seaside resorts and spas for the loss of the tax de séjour (kurtaxe) if more than 10 per cent of the available accommodation is required for patients belonging to the armed forces. Accommodation required by the child evacuation scheme, the NSV or the armed forces for other than hospital cases must not be counted, although exempt from the kurtaxe. This ruling takes effect retrospectively as from April 1, 1942. The rules regarding the waiving or reduction of the kurtaxe for members of the armed forces remain unchanged.

According to the *Frankfort Zeitung* of July 2 a spa in southwestern Germany, which may be regarded as an example for many others, was mainly used by war wounded during the first year of the war, and in the second year the number of reservations by private patients had to be restricted. All large hotels are used as war hospitals, and part of the remaining accommodation is reserved for wives of soldiers. The organization Mother and Child had to be referred to less overcrowded places, as so much accommodation is needed for the war hospitals in the town. Even so there is little accommodation to be had, the duration of each patient's stay is limited, and admittance is made conditional on a doctor's certificate. In hotels the lack of domestic and kitchen staff is made good by the employment

of prisoners of war. Soldiers are everywhere and give the impression of a garrison town. Food is still sufficient. All excursions have to be made on foot, as there are no busses running.

At a ceremony in the Gau capital, Bayreuth, Gauleiter Wachtler inaugurated the Winifred Wagner House in the presence of Frau Winifred Wagner, the leader of the NSV, Oberbefehlshaber Hilgenfeldt and the reich health leader, Dr Conti. According to DNB of July 12, this house is not an ordinary hospital but an immense scheme serving the future of the German people: it is the crowning achievement of the work for improving public health which was started in 1933. Gauleiter Wachtler declared that after the war the Winifred Wagner House is to become the center of the battle against infant mortality. Oberbefehlshaber Hilgenfeldt then handed over the House which had been sponsored by the welfare scheme Mother and Child of the NSV, to the gauleiter. "This house," he declared, "which was built on the fuhrer's own orders, not only will be a hospital but will be above all at the service of mother and child, and will be used for the training of doctors, nurses and all those who collaborate in the welfare scheme Mother and Child. Dr Conti described the Winifred Wagner House as the first large scale National Socialist hospital in the reich, as opposed to the conception of the hospital of the past."

According to NDZ of July 9, party and state are conducting a systematic fight against infant mortality also in the Upper Rhine districts of Baden and Alsace. Prof. Dr Hofmeister, who has been called from the Reich Institute for Combating Infant and Child Mortality, Berlin to the chair for child therapeutics and as head of the children's clinic at the University of Strasbourg, stated in an interview with NDZ's Strasbourg correspondent that in 1913, out of a total of 1,000 children in Baden, 138 died before their first birthday—that is, 13.8 per cent, but in 1936 in Mannheim the largest city in Baden, only 296 children out of 4,731 died—that is, 6.2 per cent. The improvement is even greater in some other towns and shows that the reich health leaders' aim to reduce infant mortality to 4 per cent is susceptible of realization.

Good results have followed the establishing of mothers' milk centers in Heidelberg, Freiburg and Karlsruhe which make the surplus milk of nursing mothers available to sickly babies. In one year over 300 infants that seemed beyond saving were kept alive in Karlsruhe through the distribution of 4,000 liters of mother's milk. However, the fight against infant mortality must not be confined to the infant but must begin with the adolescent girl, thus women are growing up everywhere who not only understand the nursing of infants but also are experienced in domestic work.

According to the *Kölnische Zeitung* of July 2 the law for the protection of motherhood applies only to women of German nationality—except Jewesses—and to women of German blood. It applies also to women who have been specially designated by the reichsführer SS in his capacity as Reichskommissar für die Festigung Deutschen Volkstums. All other women who are working in German factories and offices (including Poles, Jewesses and Gipsies) are entitled to only a certain minimum protection. They may refuse to continue work if they can prove that they are likely to be confined within two weeks, and they must not be employed for the first six weeks after their confinement. The further protective periods ordered by the law do not apply to these mothers.

In a broadcast Dr. Grasset said, according to *Havas* of July 18, he had been entrusted by Petru and Laval with the direction of the department of health. This was a heavy burden and he was addressing this appeal to the practicing doctors of France and the empire. A complete reorganization of the profession had become necessary. Doctors could give the community a greater and far more efficient help than has been the case in the past. In the near future Dr. Grasset would provide them with the framework of a corporation, established according to the marshal's ideas, which would release them from unnecessary formalities, entrust them with new responsibilities and embody them in the elite which the regime was trying to build up. Dr. Grasset had submitted to the marshal a law to safeguard the legitimate rights of all physicians still in Germany. Their release had not yet reached the desired extent. Their families should, however, know that, together with the military health services, they were applying all their efforts to make sure that, after their return, fraternal solidarity would make up to them for the bitterness of a long exile.

Seventy cases of poisoning from drinking methylated spirits recently occurred in Berlin, according to the *Stockholm Tidningen* of August 6, some of the victims died and some were blinded. Ordinary alcohol, it is said, is practically unobtainable in Germany.

Report of Medical Planning Committee of British Medical Association

Medical service in this country has grown up in a piecemeal fashion, in which private practice, philanthropy and government action have played their separate parts without any coordination. With the passage of the insurance acts government control of medical practice was greatly increased. It is generally agreed that the present system, or want of system, cannot last, but there is much difference of opinion as to its reform. As in all our institutions, the war seems likely to accelerate change. A medical planning commission established by the British Medical Association, with the cooperation of medical corporations, was appointed in August 1940 to study wartime developments and their effect on the country's medical services. The commission appointed five subject committees to deal respectively with general practice, special practice, public health, hospitals and teaching hospitals, and a sixth to coordinate the work of those committees. It adopted for the purpose of its discussion a broad definition of the objects of medical service: (1) to provide a system to achieve positive health, the prevention of disease and the relief of sickness, (2) to render available to every individual all necessary medical services, both general and specialist, and both domestic and institutional.

The commission has now published an elaborate report. It points out that the days when a doctor armed only with his stethoscope and his drugs could offer a fairly complete medical service are gone. He cannot now be all sufficient. He must have at his disposal modern facilities for diagnosis and treatment, which often cannot be provided by a private individual or installed in a private surgery. He must also have easy and convenient access to consultant and specialist opinion, whether at the hospital or elsewhere, and he must have means for real collaboration with consultants. Such facilities are now inadequate. There must also be collaboration among local practitioners, for their different interests and experiences can be of value to one another. There are insufficient facilities for regular postgraduate study and the development of special scientific and clinical interest. The pressure of work, which is in part due to bad distribution, often leads to excessive hours of duty and insufficient holidays.

Another defect is the existence side by side of two essentially different hospital systems, the individualistic voluntary hospital (so called because supported by voluntary subscription from the philanthropic) staffed by practitioners who in most cases receive no direct remuneration for their services, and the municipal hospitals under local government authorities and staffed by practitioners who are paid officers. Many of the differences between the two systems are fundamental, such as the conditions of admission of patients and the opportunities for professional careers. Their existence is detrimental to the development of an efficient hospital service.

While there is general agreement as to objects of reform, there is difference of opinion as to the way to achieve them. Some maintain that the existing system can be so rearranged as to provide a satisfactory service. Others consider that the ideals cannot be achieved without such a radical change as would replace private practitioners by whole time salaried government officials. A third group favors a combination of private practice and government service. There are, however, some fundamental principles which the commission lays down. The organization of the national health services should be based on the family as the normal unit and on the family doctor as

the normal medical attendant. The first essential is not institutional but personal service, such as can be rendered by the family doctor who has the continuous care of the health of the family. To him they will turn for advice and help. He will give them such service as he can render personally and will see that they obtain full advantage of all the further auxiliary services that may otherwise be provided.

The present uncoordinated hospital services should give way to a unified hospital system. Some reformers demand a complete state controlled hospital service which presumably would absorb the great voluntary hospitals. Others advocate a national hospital corporation to take over the voluntary and municipal hospitals and organize them into a single system. But the voluntary hospitals embody traditions which should not be allowed to disappear. At the same time the potentialities of the municipal hospitals are great and should be developed. The general view is that from the two systems there should be evolved one coordinated system embodying the best features of the two. The hospital services, the personal health services and the general practitioner services should be closely linked. The organization of all hospital services on a regional basis is generally favored.

PROPOSALS

A central authority should be established for all civilian medical and auxiliary services. This may be a government department or a corporate body formed under government auspices. It should have a medical practitioner as its chief officer and be responsible for the formulation and administration of a national health policy and the terms and conditions of service. The work of local health authorities would be purely administrative. They would control areas with a population of not usually less than half a million. Each would have an advisory medical committee. There is also a scheme for model health centers at which practitioners would attend at certain hours. There would be provided medical equipment and a secretarial and dispensing staff. This would be much more economical than the present system, in which each practitioner has to supply such requisites at his own premises.

Endemic Goiter in the State of São Paulo

Dr A. Arruda Sampaio has published the results of an extensive study of endemic goiter in preschool and school children of different areas of the state of São Paulo. The areas studied are separated into four groups: the Atlantic littoral, the low valley of the Paraíba River, the uplands of the interior (average altitude 2,000 feet) and the regions of the Mantiqueira Sierra (average altitude 5,000 feet). About 11,000 children have been examined, showing a wide variation in the incidence of the disease (5 to 60 per cent). As the littoral regions are generally considered practically free from endemic goiter, and as in the Atlantic littoral of the state of São Paulo the incidence of the disease was low (5 to 10 per cent) and the thyroid hyperplasia always mild, the author considers this morbidity rate as corresponding merely to sporadic goiter, and the morbidity rate over 10 per cent and up to 15 per cent as corresponding to a low incidence of endemic goiter. In the endemic areas, goiter is found even in the preschool age, and the incidence increases with age, being 20 per cent higher in the age group 8 to 10 years than the corresponding group of non-endemic areas. In the areas of sporadic goiter and of low and medium incidence of endemic goiter, the prevalence is higher in girls than in boys, as usual, in the ratio of 2 or 3 to 1, but this predominance is less pronounced in the areas of high incidence. Nevertheless the volume of the tumor is generally greater in the girls.

Pan American Code for the Prevention of Blindness

The first Brazilian Congress for the Prevention of Blindness, held in Rio de Janeiro in July, prepared the draft for a Pan American code for the prevention of blindness to be submitted for approval to the various nations of the Western Hemisphere. This code suggests the creation, in each nation, of a national council for the prevention of blindness, which will be in charge of the administration of (1) prevention of the contagious diseases of the eye (mainly ophthalmia neonatorum and trachoma), (2) prevention of congenital and hereditary causes of blindness (congenital syphilis and hereditary diseases and malformations of the eye), (3) prevention of occupational injuries of the eye (protection of the workmen, evaluation of the degree of disability, compensation laws), (4) ophthalmologic inspection of school children, (5) eyesight conservation classes, (6) legislation to foster and control the correct illumination of school rooms and workshops, (7) legislation to control the work of the optometrists and commerce in lenses and (8) census taking of the blind and other persons affected with eye disabilities. Through the foreign department of Brazil a copy of the suggested code will be sent within a short time to all the nations of the Western Hemisphere.

Pharmacodynamics of Coffee

Coffee is the main agricultural product of Brazil, and every phase of its utilization is now being studied. Several papers have been lately published in Brazilian medical periodicals about the pharmacodynamics of coffee. Dr. J. M. Loureiro studied the action of coffee on the muscular tonus and reflex activity of diabetic patients. All the patients included in the study were in perfect metabolic equilibrium. The cutaneous and the deep reflexes as well as the accommodation reaction were studied before and after the ingestion of 150 cc of an infusion of strong coffee. The conclusion of the author is that coffee slightly increases the neuromuscular tonicity. Using coffee as an excitant of the biliary secretion through duodenal intubation, Dr. Cleto S. Velloso ascertained that coffee does not modify the flow of bile and therefore concluded that it is not necessary to proscribe the use of this beverage to those with biliary and hepatic disturbances. Dr. Octavio Dreux studied the action of coffee on the blood level of uric acid. After many photometric measurements he concluded that the ingestion of 20 Gm of ground coffee in 200 cc of water during fasting produces a clear uricemic wave that lasts from two to three hours, when the normal level of the uric acid is reestablished.

Yellow Fever in Brazil

A recent publication of the Brazilian Federal Public Health Service gives good news about the situation of jungle yellow fever. Whereas 217 cases of the disease were discovered in 1937, 263 in 1938, 130 in 1939, 172 in 1940 and 19 in 1941, only 10 cases have been reported during the current year up to July 31. Since 1937, well over 2 million people have been immunized against the disease with vaccine prepared at the Rockefeller Laboratory of this city.

A New Treatment for Osteomyelitis

Dr. Francisco Finocchiaro of São Paulo uses the Durante-Roentgen or physiochemiotherapeutic method in the cases of osteoperiostitis and osteomyelitis due to common germs. Through the formation of secondary rays emitted by the iodine atoms reached by the primary rays a sensitization of the inflamed regions would be produced and treatment would be more effective than with either one of the two methods alone—Durante's simple iodine applications or the roentgen therapeutic method. The process can be radiologically controlled in its phases of reabsorption of the osteophytes of the peri-

ostitis, of the small sequestrums and the final churningization. Since the connecting cartilages are respected, there are no mutilations and losses of function as so frequently are found in surgical interventions. Secondary irradiations were utilized by Ghilarducci, who effected iontophoresis with silver solution. Dr. Finocchiaro replaced this process by the direct introduction of the secondary irradiator—iodine—according to Durante's formula and by the indirect, inaccessible processes by impregnation of the reticuloendothelium with colloidal silver injected into the vein. From the standpoint of time, the cosmetic results, function and operative risk, the method used by Dr. Finocchiaro should be preferred to surgery in view of the results obtained.

Reinfusion of Blood in Ruptured Ectopic Pregnancy

The reinfusion of blood in ruptured ectopic pregnancy is a widely used method in surgical centers of Brazil. A report was recently published by Dr. João Alfredo, director of the emergency service of Recife. He operated on 26 patients with ruptured ectopic pregnancy. In all these cases blood reinfusion was performed with only one death. The advantages of reinfusion with blood collected in the peritoneal cavity as performed for the first time by Thier in 1914 were emphasized by Dr. Alfredo. After the abdomen has been opened the blood is collected in a sterile syringe and injected by an assistant into a vein of the elbow. In 3 of the 26 cases reported more than 1,000 cc of blood was reinfused.

Anesthesia in Thoracic Surgery

The use of anesthesia in the operative treatment of tuberculous patients was recently described by Dr. Jesse Teixeira of Rio de Janeiro. He emphasized the advantages of the extradural administration of anesthetic drugs. The safety of this method makes it available in all thoracic surgery. Dr. Teixeira obtains the best results when the solutions are injected into the upper portion of the spine between the seventh cervical vertebra and the fourth dorsal vertebra. Anatomic conditions were reported and the questions of negative pressure and diffusion of fluids in the extradural space were discussed. A personal clearcut conception is set forth to explain the exclusive control of sensitive paths and preservation of motile mechanisms. He presented also the good effects observed postoperatively in 59 cases, in which pneumectomy was performed in 1 case, mastectomy in 2 cases, extrapleural pneumothorax in 1 case, the operation of Gray Schmidt in 2 cases, the operation of Sembr in 11 cases and partial thoracoplasties in 42 cases.

Brief Items

The health department of Petropolis, the so-called summer capital of Brazil, will be improved with the cooperation of the Pan American Sanitary Bureau in order to become the most up to date municipal health organization in the country. Petropolis, a city of about 60,000 population, is set on a plateau with an altitude of 2,000 feet and its health department will be used in the future as a demonstration unit of modern public health administration and for the training of sanitary personnel.

With the cooperation of the Brazilian Public Health Service, six tuberculosis sanatoriums and three preventoriums will be opened soon in the cities of Belém (state of Pará), Fortaleza (state of Ceará), Recife (state of Pernambuco), Natal (state of Rio Grande do Norte), Vitória (state of Espírito Santo) and Porto Alegre (state of Rio Grande do Sul).

With the aid of the federal government three more modern leprosariums have been built recently in different states of Brazil. There are now nineteen first class leprosariums and fourteen others that are not rated as good ones.

Deaths

Owing to the accumulation of material of military importance, the publication of obituaries has been somewhat delayed, hence the publication of four pages in this issue

Stephen Walter Ranson, Chicago, Rush Medical College, Chicago, 1907, associate in anatomy in 1908, assistant professor in 1909, associate professor in 1910 and professor of anatomy from 1911 to 1924 at Northwestern University Medical School, where he had been professor of neurology and director of the Neurological Research Institute since 1927, professor of neuroanatomy and head of the department of neuroanatomy and histology at the Washington University School of Medicine St. Louis, from 1924 to 1927, member and past president of the American Association of Anatomists, member of the Association for Research in Nervous and Mental Disease and the American Physiological Society, fellow of the American Association for the Advancement of Science, in 1929 the Stephen Ranson Lectureship in Medicine was created in his honor at Northwestern University, on the editorial board of the *Archives of Neurology and Psychiatry* author of the textbook "The Anatomy of the Nervous System", aged 62, died August 30 of coronary thrombosis.

Donald M. Campbell ♂ Detroit, Michigan College of Medicine, Detroit, 1885, L.R.C.P., and L.R.C.S. Edinburgh Scotland, 1886, for many years professor of ophthalmology at the Detroit College of Medicine and Surgery which is now known as the Wayne University College of Medicine where he was emeritus professor since 1937, specialist certified by the American Board of Ophthalmology and by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology the American Laryngological, Rhinological and Otolological Society and the American Otolological Society, Inc. fellow of the American College of Surgeons, honorary president of the Detroit Ophthalmological Society, president of the Wayne County Medical Society, 1914-1915 consulting ophthalmologist and otologist to the Harper Hospital and consulting ophthalmologist to the Receiving Hospital, in 1931 was awarded the honorary degree of doctor of science by the College of the City of Detroit, aged 77, died August 25.

Frederick Arthur Wild, Bound Brook N. J. University of the City of New York Medical Department, New York, 1892, member of the Medical Society of New Jersey, past president of the Somerset County Medical Society, formerly served as a member of the board of education and as county coroner, member of the draft board during World War I, past president of the board of managers of the New Jersey Sanatorium for Tuberculous Diseases, Glen Gardner, aged 74, on the staffs of the Somerset Hospital Somerville, and on the auxiliary staff of the Muhlenberg Hospital, Plainfield, where he died July 14, of carcinoma of the prostate.

David Sieber Funk, Harrisburg Pa. University of Pennsylvania Department of Medicine, Philadelphia, 1881, member of the House of Delegates of the American Medical Association in 1910, member and at one time vice president of the Medical Society of the State of Pennsylvania, past president of the Dauphin County Medical Society and the Harrisburg Academy of Medicine for many years a member and formerly president of the staff of the Harrisburg Hospital at one time member of the board of the U. S. Pension Examining Surgeons, aged 90, died, July 29, in a hospital at Richmond Va. of arteriosclerosis.

George R. Clayton, Lima, Ohio, Northwestern University Medical School, Chicago, 1898, member of the Ohio State Medical Association, specialist certified by the American Board of Ophthalmology and by the American Board of Otolaryngology, past president of the Academy of Medicine of Lima and Allen County, veteran of the Spanish-American War for many years a medical officer in the U. S. Army, aged 69, died, June 13, in the Lima Memorial Hospital.

Giles Mortimer Fleming, Cleveland N. C. Emory University School of Medicine Atlanta Ga. 1919, member of the Medical Society of the State of North Carolina, served in the medical corps of the U. S. Army during World War I for many years surgeon for the Southern Railway on the staffs of the H. I. Long Hospital, Statesville and the Rowan Memorial Hospital, Salisbury, aged 50, was found dead July 22 of coronary thrombosis.

John Rowlands Shannon, Richmond Va. Queen's University Faculty of Medicine, Kingston Ont. Canada 1890

member of the Medical Society of the State of New York and of the American Ophthalmological Society, fellow of the American College of Surgeons, served during World War I consulting ophthalmologist to the Manhattan Eye, Ear and Throat Hospital, New York, aged 78, died, July 4 of uremia.

Joseph Payne ♂ Midland Park N. J., Baltimore Medical College, 1904, formerly mayor for many years served as county physician, health officer; medical examiner for the draft board during World War I, member and vice president of the board of education, member of the board of managers of the Bergen Pines, Bergen County Hospital, Ridgewood, aged 70, died June 27 in Southold N. Y.

Bertha Estell Bush, Chicago Woman's Medical College Chicago, 1889, member of the Illinois State Medical Society, formerly instructor and assistant professor of pathology at her alma mater, on the staffs of the West Suburban Hospital, Oak Park Ill., St. Francis Hospital Evanston Ill., Ravenswood Hospital and the Women and Children's Hospital, aged 76, died July 25.

Scurry Latimer Terrell, El Paso Texas College of Physicians and Surgeons Baltimore 1895, member of the State Medical Association of Texas, served with the British Army and later in the medical corps of the U. S. Army during World War I at one time professor of otology at the Southern Methodist University Medical Department Dallas, aged 72, died July 12.

George Gustave Wallschlaeger, Milwaukee Chicago College of Medicine and Surgery 1917, member of the State Medical Society of Wisconsin, served in France as a lieutenant in the medical corps of the U. S. Army during World War I on the staffs of St. Mary's and St. Luke's hospitals, aged 50, died, July 13, of acute nephritis and chronic myocarditis.

Frank Rawlins Makemson, Bellefontaine Ohio, Ohio Medical University Columbus, 1900, past president of the Logan County Medical Society, served in the medical corps of the U. S. Army during World War I, formerly served as county coroner, aged 69, died, June 10, of aortitis, tabes dorsalis, chronic nephritis and arteriosclerosis.

Dodson, Vernon Texas, Fort Worth School of Medicine, Medical Department of Fort Worth University 1906, health officer of Vernon, formerly health officer of Wilbarger County, on the staff of Christ the King Hospital, chairman of the Health and Emergency Medical Service Civilian Defense for Wilbarger County, aged 65, died recently of coronary thrombosis.

Alphonse Ferron, Montreal, Que. Canada M.B. School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal in 1907 and M.D. in 1909, professor of clinical surgery and orthopedics at the University of Montreal Faculty of Medicine, for many years surgeon at the Hospital Notre-Dame and the Hospital Ste. Justine, died in June.

Anthime Charbonneau, Keeseville N. Y. School of Medicine and Surgery of Montreal Faculty of Medicine of the University of Laval at Montreal, 1892, member of the Medical Society of the State of New York, served as health officer for the towns of Ausable and Chesterfield and the village of Keeseville, aged 75, died June 13 of pernicious anemia.

Joseph S. Westerfield, Conway Ark. University of Louisville (Ky.) Medical Department 1880, member of the Arkansas Medical Society, secretary and past president of the Faulkner County Medical Society, formerly city and county health officer, registrar of vital statistics for the state bureau of health, aged 90, died June 28 of emphysema.

Earle Chester Hinman, Greensburg Ohio Ohio Medical University Columbus 1898, member of the Ohio State Medical Association, formerly member of the board of education, aged 76, on the staffs of the Citizens Hospital Barberton and the Peoples Hospital Akron where he died June 30 of injuries received when he fell from a ladder.

Bruce Hetrick Gustwhite, Cumberland Md. University of Maryland School of Medicine Baltimore 1914, member of the Medical and Surgical Faculty of Maryland, served during World War I for many years physician for the Baltimore and Ohio Railroad, aged 54, died June 3 in the Memorial Hospital of cerebral hemorrhage.

Roy Alfred Gregory ♂ Plainfield N. J. University of Virginia Department of Medicine, Charlottesville 1925, formerly associated with the U. S. Public Health Service on the staff of the Muhlenberg Hospital, consultant at the New Jersey State Village for Epileptics, Stillman, aged 49, died June 28 of cerebral thrombosis.

Douglas S Kistler, Wilkes-Barre, Pa Hahnemann Medical College and Hospital of Philadelphia 1893, member of the Medical Society of the State of Pennsylvania, a founder and for many years a member of the board of directors of the Wyoming Valley Homeopathic Hospital, aged 69, died, June 27, of pulmonary hemorrhage

Benjamin S White, Greensburg, Ind, College of Physicians and Surgeons, Keokuk, Iowa, 1881, member of the Indiana State Medical Association, for many years president of the city board of health and county physician, on the staff of the Decatur County Memorial Hospital, aged 87, died, July 3, of cardiac dilatation

Charles M Gibson, Pittsburg, Kan, University of Kansas School of Medicine, Kansas City, 1907, member of the Kansas Medical Society, for many years a member and at one time president of the board of education, on the staff of the Mount Carmel Hospital, aged 62, died, June 15, of hemorrhage due to carcinoma of the cecum

Albert William Ebeling, Warrenton, Mo, Homeopathic Medical College of Missouri, St Louis, 1897, formerly instructor of chemistry and physiology at the Central Wesleyan College, veteran of the Spanish-American War, aged 73, died, June 19, in the Veterans Administration Facility, Jefferson Barracks, of carcinoma

Benjamin S Swetland, Brocton, N Y, University of Buffalo School of Medicine, 1878, member of the Medical Society of the State of New York, formerly president of the old high school district of Brocton and school physician, for many years town health officer, aged 88, died, June 18, of arteriosclerosis

Thomas Jefferson Wenner ♂ Wilkes-Barre, Pa, University of Pennsylvania School of Medicine, Philadelphia 1918, member of the American Society of Clinical Pathologists, served during World War I, on the staff of the Nesbitt Memorial Hospital, Kingston, aged 48, died, June 16, of coronary disease

Emil Aronson, Dallas, Texas, University of Dorpat Faculty of Medicine, Russia, 1887, formerly clinical professor of medicine at the Baylor University College of Medicine on the staff of St Paul's Hospital from 1895 to 1940, aged 79, died, July 14, of uremia, diabetes mellitus and hypertrophy of the prostate

John C Dunn, Lewistown, Mont, Northwestern University Medical School, Chicago, 1902, formerly health officer of Fergus County, at one time medical superintendent of the Montana State Hospital, Warm Springs, aged 68, died, June 21, in Torrance, Calif, following an operation for intestinal obstruction

Joseph Augustine O'Connor, Rochester, N Y, University of Michigan Homeopathic Medical School, Ann Arbor, 1910, member of the Medical Society of the State of New York, on the staffs of the Highland and St Mary's hospitals, aged 56, died, June 11, of coronary occlusion and arteriosclerosis

Alfred Jacoby, New Orleans, Medical Department of Tulane University of Louisiana New Orleans, 1902, member of the Louisiana State Medical Society, fellow of the American College of Surgeons, visiting surgeon, Charity Hospital, aged 64, died, June 13, of subarachnoid hemorrhage and arteriosclerosis

John Wesley Tippie, Medina, Ohio, Starling-Ohio Medical College, Columbus, 1908, at one time surgeon, U S Public Health Service Reserve, serving on the staffs of the U S Veterans' Hospital, number 88, Memphis, Tenn, and the U S Veterans' Hospital number 76, Maywood, Ill, aged 55, died, June 26

Anthony Eller Klein, Corona, N Y, Georgetown University School of Medicine, Washington, D C, 1900, member of the Medical Society of the State of New York, aged 68, died, June 1, in the Queens General Hospital, Jamaica, of bronchopneumonia, cerebral thrombosis and hypertensive heart disease

Charles Munson Griswold, Milwaukee Milwaukee Medical College, 1910, veteran of the Spanish-American War and World War I, aged 68, formerly on the staff of the Veterans Administration Facility, Wood, where he died, June 12, of hypertensive cardiovascular disease and prostatic hypertrophy

George Arthur Bemis, Garner, Iowa, State University of Iowa College of Medicine, Iowa City, 1909, member of the Iowa State Medical Society, served as a captain in the medical

corps of the U S Army during World War I, aged 58, died, June 30, in a hospital at Mason City of coronary thrombosis

Omer Frank Allen ♂ Miami, Fla, Rush Medical College, Chicago 1900, for many years president of the bank in Mount Olive, Ill, and at one time physician for the Illinois Central Railroad member of the examining board during World War I, aged 72, died, August 24 following a gastroenterostomy

John Arnason Johnson ♂ Tacoma, Wash, Chicago College of Medicine and Surgery, 1910, member of the Pacific Coast Oto Ophthalmological Society, served during World War I, formerly medical examiner for the Veterans Administration, aged 65, died, June 12, of arteriosclerosis and hypertension

Edward H Cowan, Crawfordsville, Ind, Miami Medical College, Cincinnati, 1873, Civil War veteran, at one time health officer of Crawfordsville and member of the school board, for many years a member of the U S Pension Board, aged 95, died, August 1, in Dallas, Texas, of arteriosclerosis

Charles Levering Ireland, Columbus, Ohio, Cleveland Homeopathic Medical College, 1898, member of the Ohio State Medical Association, chief of physical therapy at the Walter Reed General Hospital, Washington, D C, during World War I, aged 70, died, June 10, of coronary occlusion

William Thomas Robison ♂ Murfreesboro, Tenn, Rush Medical College, Chicago, 1915, served in the medical corps of the U S Army during World War I, fellow of the American College of Surgeons, on the staff of the Rutclifford Hospital, aged 54, died, June 9, of cerebral thrombosis

Albert A Maurer, New York, Rush Medical College Chicago, 1881, member of the Medical Society of the State of Wisconsin, served as a captain in the medical corps of the U S Army during World War I, aged 83, died June 29, in a hospital near Princeton, N J, of arteriosclerosis

Vernon Albert Dean, Talco, Texas, Baylor University College of Medicine, Dallas, 1938, member of the State Medical Association of Texas, on the staff of St Joseph's Hospital, Paris, aged 33, died, June 25, in the Baylor Hospital, Dallas, of pneumonia, acute hepatitis and acute nephritis

Patrick Henry Keefe, Providence, R I, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1879, member of the Rhode Island Medical Society, fellow of the American College of Surgeons, aged 87, died, June 4, in the Charles V Chapin Hospital of arteriosclerosis

Charles D Watkins, Etna, Ohio, Columbus Medical College 1886, at one time served in the Ohio State House of Representatives and as state senator aged 77, died, June 27, in the Mount Carmel Hospital Columbus of arteriosclerotic heart disease, varicose ulcer and thrombophlebitis

Asel James Bennett ♂ Auburn, N Y, Syracuse University College of Medicine 1918, past president of the Cayuga County Medical Society, on the staffs of the City and Mercy hospitals, formerly member of the board of education, aged 49, died, June 27, of cerebral hemorrhage

John Gillison Allan, Edgewood Ill, University of Louisville (Ky) Medical Department, 1882, member of the Illinois State Medical Society, for many years president of the bank of Edgewood, aged 83, died, July 1, in St Anthony's Hospital, Effingham, of carcinoma of the tongue

Harry Burton Farnsworth, Oakland, Calif, American Medical Missionary College, Chicago 1900, fellow of the American College of Surgeons, attending surgeon, Alta Bates Hospital, Berkeley and the Providence Hospital, aged 66, died, June 4, of chronic myocarditis

Leslie Spangler Porter ♂ Portland Ore University of Oregon Medical School Portland, 1934 resident physician at the Shriners Hospital for Crippled Children formerly health officer of Coos County, aged 32, died, June 1, in Modesto, Calif, of acute pulmonary edema

Henry W Hodgson, Cumberland, Md, Washington University School of Medicine, Baltimore, 1871, past president of the Allegany-Garrett Counties Medical Society, member of the Medical and Chirurgical Faculty of Maryland, aged 96, died, June 24, of pneumonia

George Good, Union City N J, Cornell University Medical College New York, 1901 for many years on the staffs of the North Hudson Hospital, Weehawken and the Christ Hospital, Jersey City, aged 72, died, July 17, following a cholecystectomy for cholelithiasis

George Birch Clark, Armonk, N Y, Syracuse University College of Medicine 1894, member of the draft board

during World War I, aged 69, on the staff of the Northern Westchester Hospital, Mount Kisco, where he died, July 6, of carcinoma of the bladder

Armand Oliva Metivier, Chicopee Falls, Mass., College of Physicians and Surgeons, Boston, 1915, member of the Massachusetts Medical Society served in the medical corps of the U S Army during World War I, aged 52, died, July 2, of heart disease

Thomas William Tormey Ⓢ Madison, Wis., Rush Medical College, Chicago, 1902, fellow of the American College of Surgeons, on the staffs of the Madison General and St. Mary's hospitals, aged 63, died, July 8, of uremia and benign hypertrophy of the prostate

Forest Field Foster, Kansas City, Mo., University Medical College of Kansas City, 1913, member of the Missouri State Medical Association, served during World War I, aged 52, died, June 8, in Kansas City, Kan., of injuries received in an automobile accident

Leonard Riley Jenkins Ⓢ Ogden, Utah, Leland Stanford Junior University School of Medicine, San Francisco, 1916, served in the U S Navy during World War I and for four years later, aged 52, died, June 17, of diabetes mellitus and coronary heart disease

Louis S. Dunn Ⓢ Philadelphia, Medico-Chirurgical College of Philadelphia, 1907, specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology, served during World War I, aged 56, died, June 16

James Frederick Stewart Marshall, Missoula, Mont., University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1908, member of the Medical Association of Montana, served overseas during World War I, aged 54, died, June 2, of coronary occlusion

Alex D. Cameron, Kearney, Neb., Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1882, formerly served as mayor of Kearney and as county coroner, on the staff of the Good Samaritan Hospital, aged 80, died, June 29, of heart disease

William J. Steward Ⓢ Quarryville, Pa., University of Maryland School of Medicine, Baltimore, 1904, member of the American Psychiatric Association, formerly resident physician at the Polk (Pa.) State School, aged 64, died, June 20, of heart disease

Frank Ellsworth Strickling, Decatur, Ill., Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1907, member of the Illinois State Medical Society, served during World War I, aged 56, died, June 24, of chronic nephritis and uremia

William Benjamin Eason, Jackson, Tenn., Medical Department of Tulane University of Louisiana, New Orleans, 1898, member of the Tennessee State Medical Association, served during World War I, aged 66, died, June 9, of cirrhosis of the liver

Frank Edward McCullough Ⓢ Sacramento, Calif., University of Pennsylvania Department of Medicine, Philadelphia, 1906, formerly health officer of North Sacramento, served during World War I, aged 62, died, June 4, of coronary thrombosis

Frederick William Hobelmann Ⓢ Baltimore, Baltimore Medical College, 1901, for many years assistant visiting urologist at the Johns Hopkins Hospital, aged 66, died, June 14, in the Mercy Hospital of heart disease and bronchiogenic carcinoma

Noah Robert Harlan Ⓢ Freeport, Ill., Northwestern University Medical School, Chicago, 1909, fellow of the American College of Surgeons, on the staff of the Deaconess Hospital, aged 62, died, June 23, of angina pectoris and arteriosclerosis

Louis Carl Sondel Ⓢ Chicago, Bennett Medical College, Chicago, 1915, served as a first lieutenant during World War I, on the staffs of the American, Alexian Brothers' and Edge-water hospitals, aged 51, died, June 17, of coronary occlusion

William Freeman Nicholson, Hamilton, Ont., Canada, University of Toronto Faculty of Medicine, 1910, past president of the College of Physicians and Surgeons of Ontario, aged 59, died, June 3, as the result of an automobile accident

John B. Wickensimer Ⓢ Steger, Ill., Chicago College of Medicine and Surgery, 1913, served during World War I, aged 55, died, June 18, in the Veterans Administration Facility, Hines, of pulmonary tuberculosis and congestive heart failure

David Jesse Thompson, Webbville, Ky., Kentucky School of Medicine, Louisville, 1904, member of the Kentucky State Medical Association medical officer of the local Selective Service System, aged 68, died, June 25, of heart disease

Maxcy Lee Brogden, West Columbia, S. C., University of Maryland School of Medicine, Baltimore, 1909, member of the South Carolina Medical Association, aged 57, died, June 1, in the South Carolina Baptist Hospital, Columbia

Donald F. S. Smith, Atlanta, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1908, member of the Medical Association of Georgia, for many years city physician, aged 67, died, June 23, of coronary thrombosis

William W. Beveridge, Asbury Park, N. J., Bellevue Hospital Medical College, New York, 1898, member of the Medical Society of New Jersey, aged 73, died, June 10, of gangrene of both legs and chronic myocarditis

Louis Barenbaum Ⓢ Philadelphia, Temple University School of Medicine, Philadelphia, 1909, examining physician for the local draft board number 6, Selective Service System, aged 60, died, June 6, of coronary occlusion

Charles Andrew Beattie, Longmont, Colo., Hahnemann Medical College and Hospital, Chicago, 1903, served during World War I, aged 68, died recently in the Fitzsimons General Hospital, Denver, of cardiorenal disease

Charles Nathaniel Bibbins Ⓢ Watertown, N. Y., Bellevue Hospital Medical College, New York, 1894, past president of the Medical Society of the County of Jefferson, aged 75, died, June 12, of heart disease and hypertension

John F. McGuinness, Woburn, Mass., Middlesex College of Medicine and Surgery, Cambridge, 1923, member of the Massachusetts Medical Society, aged 49, died, June 17, in the Choate Memorial Hospital of myocarditis

William Ernest Crume, Bardstown, Ky., Kentucky University Medical Department, Louisville, 1905, member of the Kentucky State Medical Association, county coroner, aged 61, died, June 5, of coronary thrombosis

Francis Charles Myers Ⓢ Tulsa, Okla., University of Nashville (Tenn.) Medical Department, 1905, served overseas as a captain in the medical corps of the U S Army during World War I, aged 61, died, June 7

Oren Morrison Landon, Galesburg, Ill., State University of Iowa College of Medicine, Iowa City, 1882, at one time secretary of the board of pension examiners, aged 88, died, June 1, in Columbus, Ohio, of senility

Delmer L. Davis, Los Angeles, Hahnemann Medical College and Hospital, Chicago, 1902, at one time assistant professor of surgery at the College of Medical Evangelists, aged 66, died, June 17, of pulmonary embolism

L. Lester Williams, Mount Vernon, Ohio, Jefferson Medical College of Philadelphia, 1882, member of the Ohio State Medical Association, for many years member of the city board of education, aged 87, died, June 1

Theodore Hudson Harrell, Mission, Texas, Memphis (Tenn.) Hospital Medical College, 1901, served during World War I, specialist certified by the American Board of Pediatrics, Inc., aged 67, died, June 10

Miles Burwell Abernethy, Reidsville, N. C., North Carolina Medical College, Davidson, 1906, past president of the Rockingham County Medical Society, served during World War I, aged 61, died, June 19

Cora D. Fenton, San Diego, Calif., Cleveland Medical College, 1893, aged 82, died June 13, in the Paradise Valley Sanitarium and Hospital, National City, of pulmonary embolism and fractured neck of femur

Charles Otto Moore, Paris, Idaho, John A. Creighton Medical College, Omaha, 1914, served during World War I, aged 55, died recently in the Holy Cross Hospital, Salt Lake City, of coronary thrombosis

Robert Best, Killarney, Man., Canada, National University of Ireland 1902, aged 65, died, June 30, in the Brandon (Man.) General Hospital of pulmonary embolism and post-operative appendical abscess

James Arden Southall, Hopkinsville, Ky., College of Physicians and Surgeons, Baltimore, 1883, past president and secretary of the Christian County Medical Society, aged 82, died, June 20, of arteriosclerosis

Paul Arthur Cole, Spokane, Wash., University of Oregon Medical School, Portland, 1941, aged 30, died, June 12, of pneumonia in the Deaconess Hospital, where he had recently completed his internship

Douglas S Kistler, Wilkes-Barre, Pa, Hahnemann Medical College and Hospital of Philadelphia, 1893, member of the Medical Society of the State of Pennsylvania, a founder and for many years a member of the board of directors of the Wyoming Valley Homeopathic Hospital, aged 69, died, June 27, of pulmonary hemorrhage

Benjamin S White, Greensburg, Ind., College of Physicians and Surgeons, Keokuk, Iowa, 1881, member of the Indiana State Medical Association, for many years president of the city board of health and county physician, on the staff of the Decatur County Memorial Hospital, aged 87, died, July 3, of cardiac dilatation

Charles M Gibson, Pittsburg, Kan., University of Kansas School of Medicine, Kansas City, 1907, member of the Kansas Medical Society, for many years a member and at one time president of the board of education, on the staff of the Mount Carmel Hospital, aged 62, died, June 15, of hemorrhage due to carcinoma of the cecum

Albert William Ebeling, Warrenton, Mo., Homeopathic Medical College of Missouri, St. Louis, 1897, formerly instructor of chemistry and physiology at the Central Wesleyan College, veteran of the Spanish-American War, aged 73, died, June 19, in the Veterans Administration Facility, Jefferson Barracks, of carcinoma

Benjamin S Sweetland, Brocton, N. Y., University of Buffalo School of Medicine, 1878, member of the Medical Society of the State of New York, formerly president of the old high school district of Brocton and school physician, for many years town health officer, aged 88, died, June 18, of arteriosclerosis

Thomas Jefferson Wenner ♂ Wilkes-Barre, Pa., University of Pennsylvania School of Medicine Philadelphia 1918, member of the American Society of Clinical Pathologists, served during World War I, on the staff of the Nesbitt Memorial Hospital, Kingston, aged 48, died, June 16, of coronary disease

Emil Aronson, Dallas, Texas, University of Dorpat Faculty of Medicine, Russia, 1887, formerly clinical professor of medicine at the Baylor University College of Medicine, on the staff of St. Paul's Hospital from 1895 to 1940, aged 79, died, July 14, of uremia, diabetes mellitus and hypertrophy of the prostate

John C Dunn, Lewistown, Mont., Northwestern University Medical School, Chicago, 1902, formerly health officer of Fergus County, at one time medical superintendent of the Montana State Hospital, Warm Springs, aged 68, died, June 21, in Torrance, Calif., following an operation for intestinal obstruction

Joseph Augustine O'Connor, Rochester, N. Y., University of Michigan Homeopathic Medical School, Ann Arbor, 1910, member of the Medical Society of the State of New York, on the staffs of the Highland and St. Mary's hospitals, aged 56, died, June 11, of coronary occlusion and arteriosclerosis

Alfred Jacoby, New Orleans, Medical Department of Tulane University of Louisiana, New Orleans, 1902, member of the Louisiana State Medical Society, fellow of the American College of Surgeons, visiting surgeon Charity Hospital, aged 64, died, June 13, of subarachnoid hemorrhage and arteriosclerosis

John Wesley Tippie, Medina, Ohio, Starling-Ohio Medical College, Columbus, 1908, at one time surgeon, U. S. Public Health Service Reserve, serving on the staffs of the U. S. Veterans' Hospital, number 88, Memphis, Tenn., and the U. S. Veterans' Hospital number 76, Maywood, Ill., aged 55, died, June 26

Anthony Eller Klein, Corona, N. Y., Georgetown University School of Medicine, Washington, D. C., 1900, member of the Medical Society of the State of New York, aged 68, died, June 1, in the Queens General Hospital, Jamaica, of bronchopneumonia, cerebral thrombosis and hypertensive heart disease

Charles Munson Griswold, Milwaukee, Milwaukee Medical College, 1910, veteran of the Spanish-American War and World War I, aged 68, formerly on the staff of the Veterans Administration Facility, Wood, where he died, June 12, of hypertensive cardiovascular disease and prostatic hypertrophy

George Arthur Bemis, Garner, Iowa, State University of Iowa College of Medicine, Iowa City, 1909, member of the Iowa State Medical Society, served as a captain in the medical

corps of the U. S. Army during World War I, aged 58, died June 30, in a hospital at Mason City of coronary thrombosis

Omer Frank Allen ♂ Miami, Fla., Rush Medical College, Chicago 1900, for many years president of the bank in Mount Olive, Ill., and at one time physician for the Illinois Central Railroad, member of the examining board during World War I, aged 72, died, August 24, following a gastroenterostomy

John Arnason Johnson ♂ Tacoma, Wash., Chicago College of Medicine and Surgery, 1910, member of the Pacific Coast Oto-Ophthalmological Society, served during World War I, formerly medical examiner for the Veterans Administration, aged 65, died, June 12, of arteriosclerosis and hypertension

Edward H Cowan, Crawfordsville, Ind., Miami Medical College, Cincinnati, 1873, Civil War veteran, at one time health officer of Crawfordsville and member of the school board, for many years a member of the U. S. Pension Board, aged 95, died, August 1, in Dallas, Texas, of arteriosclerosis

Charles Levering Ireland, Columbus, Ohio, Cleveland Homeopathic Medical College, 1898, member of the Ohio State Medical Association, chief of physical therapy at the Walter Reed General Hospital, Washington, D. C., during World War I, aged 70, died, June 10, of coronary occlusion

William Thomas Robison ♂ Murfreesboro, Tenn., Rush Medical College, Chicago, 1915, served in the medical corps of the U. S. Army during World War I, fellow of the American College of Surgeons, on the staff of the Rutherford Hospital, aged 54, died, June 9, of cerebral thrombosis

Albert A Maurer, New York, Rush Medical College, Chicago, 1881, member of the Medical Society of the State of Wisconsin, served as a captain in the medical corps of the U. S. Army during World War I, aged 83, died, June 29, in a hospital near Paterson, N. J., of arteriosclerosis

Vernon Albert Dean, Talco, Texas, Baylor University College of Medicine, Dallas, 1938, member of the State Medical Association of Texas, on the staff of St. Joseph's Hospital, Paris, aged 33, died, June 25, in the Baylor Hospital, Dallas, of pneumonia, acute hepatitis and acute nephritis

Patrick Henry Keefe, Providence, R. I., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1879, member of the Rhode Island Medical Society, fellow of the American College of Surgeons, aged 87, died, June 4, in the Charles V. Chapin Hospital of arteriosclerosis

Charles D Watkins, Etna, Ohio, Columbus Medical College, 1886, at one time served in the Ohio State House of Representatives and as state senator, aged 77, died, June 27, in the Mount Carmel Hospital, Columbus, of arteriosclerotic heart disease, varicose ulcer and thrombophlebitis

Asel James Bennett ♂ Auburn, N. Y., Syracuse University College of Medicine, 1918, past president of the Cayuga County Medical Society, on the staffs of the City and Mercy hospitals, formerly member of the board of education, aged 49, died, June 27, of cerebral hemorrhage

John Gillison Allan, Edgewood, Ill., University of Louisville (Ky.) Medical Department 1882, member of the Illinois State Medical Society, for many years president of the bank of Edgewood, aged 83, died, July 1, in St. Anthony's Hospital, Effingham, of carcinoma of the tongue

Harry Burton Farnsworth, Oakland, Calif., American Medical Missionary College, Chicago, 1900, fellow of the American College of Surgeons, attending surgeon Alta Bates Hospital, Berkeley, and the Providence Hospital, aged 66, died, June 4, of chronic myocarditis

Leslie Spangler Porter ♂ Portland, Ore., University of Oregon Medical School, Portland 1914, resident physician at the Shriners Hospital for Crippled Children, formerly health officer of Coos County, aged 32, died, June 1, in Modesto, Calif., of acute pulmonary edema

Henry W Hodgson, Cumberland, Md., Washington University School of Medicine, Baltimore, 1871, past president of the Allegheny-Garrett Counties Medical Society, member of the Medical and Chirurgical Faculty of Maryland, aged 96, died, June 24, of pneumonia

George Good, Union City, N. J., Cornell University Medical College, New York, 1901, for many years on the staffs of the North Hudson Hospital, Weehawken, and the Christ Hospital, Jersey City, aged 72, died, July 17, following a cholecystectomy for cholelithiasis

George Birch Clark, Armonk, N. Y., Syracuse University College of Medicine, 1894, member of the draft board

during World War I, aged 69, on the staff of the Northern Westchester Hospital, Mount Kisco, where he died, July 6, of carcinoma of the bladder

Armand Oliva Metivier, Chicopee Falls, Mass., College of Physicians and Surgeons, Boston, 1915, member of the Massachusetts Medical Society served in the medical corps of the U S Army during World War I, aged 52, died, July 2, of heart disease

Thomas William Tormey, Madison, Wis., Rush Medical College, Chicago, 1902, fellow of the American College of Surgeons, on the staffs of the Madison General and St Mary's hospitals, aged 63, died, July 8, of uremia and benign hypertrophy of the prostate

Forest Field Foster, Kansas City, Mo., University Medical College of Kansas City, 1913, member of the Missouri State Medical Association, served during World War I, aged 52, died, June 8, in Kansas City, Kan., of injuries received in an automobile accident

Leonard Riley Jenkins, Ogden, Utah, Leland Stanford Junior University School of Medicine, San Francisco, 1916, served in the U S Navy during World War I and for four years later, aged 52, died, June 17, of diabetes mellitus and coronary heart disease

Louis S Dunn, Philadelphia, Medico-Chirurgical College of Philadelphia, 1907, specialist certified by the American Board of Otolaryngology, member of the American Academy of Ophthalmology and Otolaryngology, served during World War I, aged 56, died, June 16

James Frederick Stewart Marshall, Missoula, Mont., University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1908, member of the Medical Association of Montana, served overseas during World War I, aged 54, died, June 2, of coronary occlusion

Alex D Cameron, Kearney, Neb., Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1882, formerly served as mayor of Kearney and as county coroner, on the staff of the Good Samaritan Hospital, aged 80, died, June 29, of heart disease

William J Steward, Quarryville, Pa., University of Maryland School of Medicine, Baltimore, 1904, member of the American Psychiatric Association, formerly resident physician at the Polk (Pa.) State School, aged 64, died, June 20, of heart disease

Frank Ellsworth Strickling, Decatur, Ill., Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1907, member of the Illinois State Medical Society, served during World War I, aged 56, died, June 24, of chronic nephritis and uremia

William Benjamin Eason, Jackson, Tenn., Medical Department of Tulane University of Louisiana, New Orleans, 1898, member of the Tennessee State Medical Association, served during World War I, aged 66, died, June 9, of cirrhosis of the liver

Frank Edward McCullough, Sacramento, Calif., University of Pennsylvania Department of Medicine, Philadelphia, 1906, formerly health officer of North Sacramento, served during World War I, aged 62, died, June 4, of coronary thrombosis

Frederick William Hobelmann, Baltimore, Baltimore Medical College, 1901, for many years assistant visiting urologist at the Johns Hopkins Hospital, aged 66, died, June 14, in the Mercy Hospital of heart disease and bronchiogenic carcinoma

Noah Robert Harlan, Freeport, Ill., Northwestern University Medical School, Chicago, 1909, fellow of the American College of Surgeons, on the staff of the Deaconess Hospital, aged 62, died, June 23, of angina pectoris and arteriosclerosis

Louis Carl Sondel, Chicago, Bennett Medical College, Chicago, 1915, served as a first lieutenant during World War I, on the staffs of the American, Alexian Brothers' and Edgewater hospitals, aged 51, died, June 17, of coronary occlusion

William Freeman Nicholson, Hamilton, Ont., Canada, University of Toronto Faculty of Medicine, 1910, past president of the College of Physicians and Surgeons of Ontario, aged 59, died, June 3, as the result of an automobile accident

John B Wickensimer, Steger, Ill., Chicago College of Medicine and Surgery, 1913, served during World War I, aged 55, died, June 18, in the Veterans Administration Facility, Hines, of pulmonary tuberculosis and congestive heart failure

David Jesse Thompson, Webbville, Ky., Kentucky School of Medicine, Louisville, 1904, member of the Kentucky State Medical Association, medical officer of the local Selective Service System, aged 68, died, June 25, of heart disease

Maxcy Lee Brogden, West Columbia, S C, University of Maryland School of Medicine, Baltimore, 1909, member of the South Carolina Medical Association, aged 57, died, June 1, in the South Carolina Baptist Hospital, Columbia

Donald F S Smith, Atlanta, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1908, member of the Medical Association of Georgia, for many years city physician, aged 67, died, June 23, of coronary thrombosis

William W Beveridge, Asbury Park, N J, Bellevue Hospital Medical College, New York, 1898, member of the Medical Society of New Jersey, aged 73, died, June 10, of gangrene of both legs and chronic myocarditis

Louis Barenbaum, Philadelphia, Temple University School of Medicine, Philadelphia, 1909, examining physician for the local draft board number 6, Selective Service System, aged 60, died, June 6, of coronary occlusion

Charles Andrew Beatle, Longmont, Colo., Hahnemann Medical College and Hospital, Chicago, 1903, served during World War I, aged 68, died recently in the Fitzsimons General Hospital, Denver, of cardiorenal disease

Charles Nathaniel Bibbins, Watertown, N Y, Bellevue Hospital Medical College, New York, 1894, past president of the Medical Society of the County of Jefferson, aged 75, died, June 12, of heart disease and hypertension

John F McGuinness, Woburn, Mass., Middlesex College of Medicine and Surgery, Cambridge, 1923, member of the Massachusetts Medical Society, aged 49, died, June 17, in the Choate Memorial Hospital of myocarditis

William Ernest Crume, Bardstown, Ky., Kentucky University Medical Department, Louisville, 1905, member of the Kentucky State Medical Association, county coroner, aged 61, died, June 5, of coronary thrombosis

Francis Charles Myers, Tulsa, Okla., University of Nashville (Tenn) Medical Department, 1905, served overseas as a captain in the medical corps of the U S Army during World War I, aged 61, died, June 7

Oren Morrison Landon, Galesburg, Ill., State University of Iowa College of Medicine, Iowa City, 1882, at one time secretary of the board of pension examiners, aged 88, died, June 1, in Columbus, Ohio, of senility

Delmer L Davis, Los Angeles, Hahnemann Medical College and Hospital, Chicago, 1902, at one time assistant professor of surgery at the College of Medical Evangelists, aged 66, died, June 17, of pulmonary embolism

L Lester Williams, Mount Vernon, Ohio, Jefferson Medical College of Philadelphia, 1882, member of the Ohio State Medical Association, for many years member of the city board of education, aged 87, died, June 1

Theodore Hudson Harrell, Mission, Texas, Memphis (Tenn) Hospital Medical College, 1901, served during World War I, specialist certified by the American Board of Pediatrics, Inc, aged 67, died, June 10

Miles Burwell Abernethy, Reidsville, N C, North Carolina Medical College, Davidson, 1906, past president of the Rockingham County Medical Society, served during World War I, aged 61, died, June 19

Cora D Fenton, San Diego, Calif., Cleveland Medical College, 1893, aged 82, died, June 13, in the Paradise Valley Sanitarium and Hospital, National City, of pulmonary embolism and fractured neck of femur

Charles Otto Moore, Paris, Idaho, John A Creighton Medical College, Omaha, 1914, served during World War I, aged 55, died recently in the Holy Cross Hospital, Salt Lake City, of coronary thrombosis

Robert Best, Killarney, Man., Canada, National University of Ireland, 1902, aged 65, died, June 30, in the Brandon (Man.) General Hospital of pulmonary embolism and post-operative appendical abscess

James Arden Southall, Hopkinsville, Ky., College of Physicians and Surgeons, Baltimore, 1883, past president and secretary of the Christian County Medical Society, aged 82, died, June 20, of arteriosclerosis

Paul Arthur Cole, Spokane, Wash., University of Oregon Medical School, Portland, 1941, aged 30, died, June 12, of pneumonia in the Deaconess Hospital, where he had recently completed his internship

Cassius Lightner Campbell, Atlantic Iowa Miami Medical College, Cincinnati, 1881, member of the Iowa State Medical Society, aged 85, died, June 16, in the Atlantic Hospital of cerebral hemorrhage

George Leo Weiler, Salt Lake City, George Washington University School of Medicine, Washington, D. C., 1909, veteran of the Spanish-American War, aged 65, died, June 24 of coronary thrombosis

John Richard Shannon, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia 1896, veteran of the Spanish-American War, aged 72, died, June 18, of chronic myocarditis

Willis Eldredge King, Sacramento Calif., University of Pennsylvania Department of Medicine, Philadelphia, 1896, aged 68, died, June 9, in the Sutter Hospital of arteriosclerosis and chronic myocarditis

Henry Oliver Beeson, San Bernardino, Calif., Kansas City (Mo.) Medical College 1880 member of the California Medical Association, aged 89, died recently of diabetes mellitus and acute nephritis

Charles Oliver Henry, Fairmont W. Va. College of Physicians and Surgeons, Baltimore 1882, member and past president of the West Virginia State Medical Association aged 85, died, June 20

Luther E. Evans, West Jefferson Ohio, Stirling Medical College, Columbus, 1900 for many years a member of the board of education, aged 67, died, June 25, of bronchopneumonia and diabetes mellitus

Benjamin Warren Vaughan, Columbia Mo., University of Missouri School of Medicine, Columbia, 1901, aged 65, died June 7, in Kansas City of cerebral hemorrhage and hypostatic pneumonia

George James Goodin, Detroit Ill., Keokuk (Iowa) Medical College College of Physicians and Surgeons, 1907, on the staff of the Illinois Community Hospital, Pittsfield, aged 58, died June 29

James Fife Fisher, Sylvania Ohio Stirling Medical College Columbus, 1900, member of the Ohio State Medical Association, aged 68, died June 4, of chronic interstitial nephritis with uremia

Charles Edgar Harvey, Greenport N. Y., New York Homeopathic Medical College and Hospital, New York, 1907 aged 72 died, June 21, in the Eastern Long Island Hospital of nephritis

William Burnham Fisk, Oak Park, Ill., Northwestern University Medical School, Chicago 1898, member of the Illinois State Medical Society, aged 71, died in June, of coronary occlusion

Arthur Stephenson Spangler, Pauls Valley Okla. University of the South Medical Department, Sewanee Tenn. 1904 also a druggist, aged 68, died June 22, of pulmonary embolism

Howard George Hunsberger, Mount Hope, Kan., University Medical College of Kansas City, Mo. 1901, served during World War I, aged 67, died, June 1, of coronary occlusion

Camillus F. Eason, Hickory Va., University College of Medicine Richmond, 1897, for many years member of the county board of health, aged 65 died, June 4, of coronary occlusion

Joseph Francis Steininger * Gary, Ind., University of Illinois College of Medicine, Chicago, 1939, aged 29, was drowned while fishing in Miner Lake near Allegan Mich., June 30

William W. Swarts, Wichita Falls Texas Physio Medical College of Indiana Indianapolis 1893 on the staff of the Wichita General Hospital, aged 77, died, June 3 of angina pectoris

Byron B. Hauser, Hooper, Neb. College of Physicians and Surgeons, Baltimore 1898 member of the Nebraska State Medical Association, aged 70 died June 14, of diabetes mellitus

Julius Propper * Philadelphia Medico Chirurgical College of Philadelphia, 1904, aged 63, died, June 27, in the Memorial Hospital of coronary thrombosis and carcinoma of the bladder

Henry James Matthews * Nicholville N. Y., University of Vermont College of Medicine, Burlington 1879, on the staff of the Potsdam (N. Y.) Hospital, aged 87, died, June 28, of uremia

Charles Andrew Inks * Nappanee, Ind., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902, aged 66, died, June 21, of heart disease

James Louis Post, Van Buren, Ark., St. Louis University School of Medicine, 1907, member of the Arkansas Medical Society, aged 59, died recently of cardiovascular renal disease

Boze B. Kitchens, Mitchell, Ga., University of Georgia Medical Department, Augusta, 1884, aged 87, died, June 27, in the Rawlings Sanitarium Sandersville, of prostatic disease

Harry Leonard Merscher, Philadelphia, Jefferson Medical College of Philadelphia, 1910, aged 54, died, June 21, in the Lankenau Hospital of acute cholecystitis with perforation

Frank Prior Hardy, Searcy, Ark., University of Arkansas School of Medicine, Little Rock, 1913, member of the Arkansas Medical Society, aged 55, died June 22, of lymphatic leukemia

William S. Gates, Ludington, Mich. Chicago Medical College 1881, aged 86, died June 29 in the Paulina Stearns Hospital of aneurysm of the abdominal aorta with thrombosis

Frederick Rosenfeld, New Gardens N. Y., Kaiser Wilhelms-Universität Medizinische Fakultät Strassburg, Germany, 1900, aged 65, died, June 12 of cerebral hemorrhage

Arthur Blackwell Cosby, Big Island Va., Medical College of Virginia, Richmond 1895, member of the Medical Society of Virginia, aged 70, died June 26, of heart disease

Henry Stevens Kiersted, San Francisco, University of Pennsylvania Department of Medicine Philadelphia 1893, aged 69, died recently of chronic myocarditis and arteriosclerosis

Albert Olen Menefee, Tatum, Texas, Medical Department of Tulane University of Louisiana New Orleans 1890, aged 77, died, June 12 in a hospital at Dallas of heart disease

William A. Berry, Ashland, Ky. Hospital College of Medicine Louisville 1887, member of the Boyd County Health Department, formerly a druggist aged 80, died June 23

Rufus W. Ratliff, Jonesboro Ark. Memphis (Tenn.) Hospital Medical College, 1900, member of the Arkansas Medical Society, aged 77, died, June 23, in St. Bernard's Hospital

Stephen Fleming, Lincoln Calif. College of Physicians and Surgeons of San Francisco 1912, aged 64, died, June 12, in the Humboldt County Hospital of coronary thrombosis

Thomas M. Nimmo, Easton, Ky., University of Louisville Medical Department 1895 for many years local surgeon for the Illinois Central Railroad aged 80 died June 22

David Thomas Lesher, Williamsport Md. Jefferson Medical College of Philadelphia 1880 aged 88 died June 1, in Hagerstown of chronic myocarditis and arteriosclerosis

Jacob Louis Winner, Baltimore, Baltimore Medical College 1893, member of the Medical and Surgical Faculty of Maryland aged 70 died June 21, of arteriosclerosis

Michael Phillip Cannon * Chicago Chicago College of Medicine and Surgery, 1916 aged 65 died, June 1, in Ocala Fla. of coronary thrombosis and hypertension

Samuel Hubbard Gaines, Lucien Okla. Chattanooga (Tenn.) Medical College, 1906 aged 59, died June 1

George W. Longenecker * Lincoln Kan. Kansas City (Mo.) Medical College 1902, aged 66, died June 10

DIED IN MILITARY SERVICE

Thomas Anthony Martin, Providence, R. I. Jefferson Medical College of Philadelphia, 1935, member of the Rhode Island Medical Society and of the New England Obstetrical and Gynecological Society was a first lieutenant in the medical corps reserve and was called to active duty Feb. 24, 1941 as a captain in the Rhode Island National Guard Medical Detachment 103d Field Artillery 43d Division stationed at Camp Blanding, Fla. aged 32 died August 4, in the Walter Reed General Hospital Washington, D. C. of lymphosarcoma

Brunson Burns Matthews, Shelby, N. C., Medical College of the State of South Carolina Charleston 1927 formerly public health officer of Andalusia Ala., was called to active duty as a captain in the medical corps of the U. S. Army July 10 1942, was stationed at Camp Blanding Fla. where he died in the Station Hospital August 3 of bilateral pulmonary embolism secondary to bronchopneumonia aged 39

Bureau of Investigation

PHILLIPS ALIAS PHILLIPS

Criminal Impersonates His Former Medical Corps Superior

A man named Phillips, although not a doctor of medicine and not licensed to practice anywhere, was able to hold a position temporarily as chief resident and chief assistant surgeon at the Enloe Hospital, Chico, Calif. His record attracted wide attention.

As with many others who engage in a criminal career a relatively insignificant detail resulted in his apprehension. J. W. Williams, special agent for the California State Board of Medical Examiners, was going through some prescriptions in connection with another case and noted some 200 prescriptions which were incompletely filled out and signed by Phillips. When interviewed by the agent Phillips readily admitted that he was not licensed in California but pleaded ignorance of the laws

to have been medical director of the Soil Conservation Service in New Mexico, and, prior to his arrival in Chico in April 1942 contract surgeon in the Civilian Conservation Corps.

Inquiry addressed to the West Virginia Public Health Council indicated that Phillips had never been licensed to practice medicine in that state, and the University of Tennessee College of Medicine advised that he appeared to be an impostor to whom a copy of the diploma of James Herman Phillips, M.D. of Dora, Ala., had been issued in 1930 on receipt of an affidavit stating that he had lost the original in Europe during World War I.

Phillips was arrested at Chico May 26, 1942 and interrogated for approximately three hours. During this time he signed a fourteen page statement in which he confessed to being an impostor, stating that he had never attended medical school, that his diploma was obtained on false affidavit and, further, that he was an ex-convict with a long criminal record and that his true name was Arthur Osborne Phillips.

Phillips claimed that the diploma was in the possession of the prosecuting attorney at Murphy, Idaho who had taken it

Reproduction of a draft for fake diploma 1923

Chico Calif 1942

Murphy Idaho 1937

and claimed to have held similar positions in eastern hospitals without a license. He claimed, however, that he had graduated from the University of Tennessee College of Medicine on June 8, 1916 and was licensed to practice in West Virginia in 1929 but stated that this license had become delinquent because of nonpayment of tax in 1932.

Phillips claimed, further, to have been deputy state commissioner of public health in Indiana in 1916 and 1917, to have been employed by the Division of Industrial Hygiene and Medicine of the federal government, 1918-1920, to have been director of the medical department of the Ford Motor Company, Detroit, 1920-1921, and medical director of the Wallis Tractor Company and Racine Auto Tire Company, Racine, Wis., and the Fuller Construction Company, Cumberland Md., for a period of one year each, from 1922 to 1924. He stated that he had been employed by the W. F. Prior Company of Hagerstown, Md., where he claimed to have directed research work until 1926. From 1926 to 1929 he claimed to have served as a resident in various institutions, including Johns Hopkins at Baltimore, the Newcomb Hospital, Vineland, N. J., and the Franklin Square Hospital at Baltimore, to have practiced in West Virginia in 1929 and 1930, to have been employed by the federal government as director of industrial medicine in Washington, D. C.,

to return to the University of Tennessee College of Medicine after Phillips was convicted and sentenced to serve from one to fourteen years in the state prison for impersonating a practitioner of medicine.

Phillips stated that he was a high school graduate had taken a special course in biology and bacteriology, correspondence courses in placer mining and soil and water conservation from a WPA project school in Idaho and also correspondence courses in agriculture and home economics. He claimed to have attended medical school at the University of Buffalo in 1915 and 1916 but later admitted that this statement was false. This is an interesting claim, in view of the diploma draft reproduced herewith, taken from the files of the Bureau of Investigation. He attempted to have the diploma made in 1923 giving as his address at that time Box 1733 Atlanta Ga. this being his cell number in the Atlanta Federal Prison in which he was then confined.

A complete record of all his known convictions appears in the accompanying table as given by the California authorities. It is interesting to compare periods of imprisonment with the positions he claimed to have held during those periods.

In 1918 he served as a private in the Army Medical Corps as an orderly under the real J. H. Phillips M.D. In 1921 the

latter entered an institution, in which he is still located. Subsequent to this, the impostor visited Dr Phillips' family in Alabama and is alleged to have taken the diploma and license, which were on the walls of the room which he occupied.

In 1930 he appears to have served for a short time as an intern at St Francis Hospital, Charleston, W Va, but was discharged because of unprofessional conduct and because there was some question concerning his professional education and licensure.

When arrested, Phillips had in his possession membership cards issued to James Herman Phillips, MD, for 1930 and 1931 by the West Virginia State Medical Association and Central Tri-State Medical Association of Ohio, Virginia and West Virginia. The records indicate that for one year he was a member of the Kanawha Medical Society and the West Virginia State Medical Association but was dropped, Jan 1, 1931, for advertising and general attitude.

Subsequent to his release from Atlanta in 1934 he attempted to obtain reciprocity licenses in Maryland, West Virginia, South Dakota, Iowa, Colorado, Montana, Idaho, Pennsylvania, Minnesota, New Jersey, New Mexico and California on the basis of his fraudulent University of Tennessee College of Medicine

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," or medical devices have agreed with the Federal Trade Commission to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Air Way Reducing Girdle—Discontinuance of this designation or any other representation that the wearing of the device will cause a definite reduction in weight or measurement or a loss of fatty tissue was agreed to by the Physicians Supply Company Inc, San Diego Calif, in a stipulation that it signed with the Federal Trade Commission in August 1941. The concern further stipulated that it would no longer represent that this or any other girdle that it sells is nonabsorbent or that the possibility of skin infection from excreted waste matter absorbed by a girdle is eliminated by wearing this particular one.

diploma and credentials fraudulently obtained from the Alabama Board of Medical Examiners.

In 1936 he applied for a fellowship in the Mayo Foundation.

When he was arrested in Chico and taken to his own car an opening of the glove compartment revealed a revolver. He was unable to explain his possession of this weapon, which he as an ex-convict would not be allowed to possess in California. He was booked in the Chico city jail on a charge of violating section 2141 of the Business and Professions Code and remained in jail, in lieu of a \$1,000 cash bail, until the following day, when he appeared before a justice of the peace and pleaded guilty to the charges. He was rebooked on a felony charge for possession of concealed weapons. On May 28 he was sentenced to the maximum penalty for practicing medicine without a license in California—six months in the county jail and \$600 fine, and on June 29 he was sentenced to serve nine months in the Butte County jail for possession of firearms, this sentence to run concurrently with the other.

Much of the information reproduced herewith directly from the California report is authenticated from the files of the American Medical Association. Reproduced herewith are photographs taken of Phillips at Murphy, Idaho, in 1937 and at Chico, Calif, in 1942.

The most amazing feature of this story is not the man's colossal impudence and foolhardiness but rather the fact that he was able to conduct himself in an operating room in such a way as to avoid suspicion and yet was apprehended because of his incomplete prescriptions.

Allergy Electric Mask—The Federal Trade Commission announced in August 1941 that the Allergy Research Institute Inc Cincinnati had entered into a stipulation in regard to some of the claims made for

Allergy Electric Mask and "Allergy Electric Mask Filter" for treatment of hay fever, rose fever and seasonal asthma. Subsequently (November 1941) the Commission announced that Ralph Hess of Cincinnati who handled the advertising for Allergy Electric Mask had agreed to cease representing that the device will prevent or cure or be a medical treatment for hay fever, rose fever or seasonal asthma will purify or completely filter the air breathed or prevent pollens and molds from reaching the sensitive membranes.

Perspirator—This Turkish bath cabinet was put out by an Irene G Fenton trading as Perspirator Manufacturing Company Toledo Ohio. In August 1941 this person stipulated with the Federal Trade Commission that she would discontinue the following misrepresentations in the sale of her cabinet: that the use of this device will rejuvenate the entire system; that it is a cure or remedy for excess weight or keeps the pores open or induces elimination of body poisons; that it will give relief to the nervous manifestations attending menopause; that it will cure or break up colds or correct sallow sluggish skin or blackheads and other skin blemishes; that it is a cure or remedy for symptoms of overindulgence or corrects rheumatism lumbago arthritis and muscular pains. Irene G Fenton further stipulated that in the future her advertisements would not fail to reveal that normal persons may faint and be seriously burned when using her cabinet unattended.

Spalding's Wonder Plasters—These were put out by Spalding Plaster Company Inc Providence R I, which stipulated with the Federal Trade Commission in September 1941 to discontinue the following misrepresentations: that these plasters will remedy or cure rheumatism, arthritis neuritis or other ailments or will be of any benefit in such conditions beyond the temporary relief of painful symptoms; that they will restore normal circulation throughout the system or affect the circulation aside from stimulating it at the site of application; or that the plasters are entirely different from competing products or that the principle involved in the Spalding Method is unique or new.

Correspondence

ESSENTIAL HYPERTENSION

To the Editor—The report of the Council on Pharmacy and Chemistry prepared by Goldblatt, Kahn and Lewis in *THE JOURNAL*, August 8, is an unusually complete survey of the hypertension problem but ignores the weight of recent evidence for the view that essential hypertension in man is fundamentally different from any of the human or experimental types of hypertension which from their outset are associated with organic renal lesions or with organic obstruction to flow in the renal artery or the abdominal aorta proximal to a renal artery.

It mentions but does not sufficiently emphasize that essential hypertension in man is often unstable, present only under stress, and may disappear for months or years under dietetic, psychotherapeutic or mild sedative management. It ignores the probability that certain cases of human hypertension have adrenal cortex hyperplasia and overactivity as the fundamental defect, and that desoxycorticosterone causes a nonrenal hypertension similar to the hypertension of Cushing's syndrome. Renal arteriosclerosis is assumed by the authors to underlie nearly all cases of benign essential hypertension. They include the proviso "If the idea is correct that renal arteriosclerosis and arteriolar sclerosis are the morphologic bases of most cases of so-called essential hypertension in man" but ignore the imposing body of evidence that this supposition is fallacious. The result is to give an undeservedly pessimistic outlook on the prognosis in individual cases of hypertension today, and on the utility of seeking improved therapy for a condition which, to the authors, is an inescapable sequel of involutional changes in the renal vascular bed.

Conceding that unilateral renal arterial narrowing may lead to arteriosclerosis in the opposite kidney in those species, including man, in which such a stenosis causes hypertension, the Council report quietly ignores the obvious fact that the renal arteriosclerosis seen in many human cases of hypertension may also be a sequel to the hypertension and not the "basic cause." Any one who follows the retinal vascular changes in human hypertensives is aware of the fact that they progress slowly in those who tolerate hypertension for years or decades but go to pieces rapidly in those who show evidence of rapidly progressing arteriosclerosis of the kidney. The Council's authorities can scarcely hope to persuade us that retinal arterial disease is not dependent in many cases on hypertension and that it cannot retrogress when hypertension is abolished, or that renal arteriosclerosis is a disease which invariably precedes hypertension, progresses with relentless course uninfluenced by hypertension or else remains stationary in spite of the high blood pressure and advancing age of the patient. Yet only this last supposition will account for the many women, and somewhat less numerous men, who have definite hypertension for decades and yet show minimal renal or retinal vascular changes.

Studies of kidneys post mortem and of renal blood flow during life indicate that significant organic narrowing of the renal vascular bed never occurs in most cases of essential hypertension and only terminally in a few. Improvement of both renal and retinal conditions after splanchnicectomy indicates that renal arteriosclerosis is an "accessory factor," not the basic cause, of the disease and that even when well defined this accessory factor is usually of secondary importance. The dogmatic assertion that renal arteriosclerosis, a spontaneous, uncontrollable involution of the vessels, underlies "most" cases of essential hypertension is in flat contradiction to the facts and is equally destructive of the morale of the hypertensive physician, the treatment of his patients and the prosecution of research in this field. While the Council's dissatisfaction with all present methods of therapy is largely justified, the Council is not justifi-

fied in ignoring the insecure basis of the underlying philosophy of the report itself. The profession should not be given nihilistic dogma without reference to such contrary views as have been ably summarized in the Croonian Lectures for 1941 or to the actual data on the renal vascular bed in hypertension which has been accumulated in recent years.

WILLIAM DOCK, M D, New York

Professor of Pathology, Cornell
University Medical College

To the Editor—Reports of toxic reactions and an occasional death following thiocyanate therapy in hypertension tend to emphasize the need for care in the selection of patients for treatment and in their supervision while receiving this drug.

Many of the pharmacologic properties of thiocyanates have been reviewed in the several publications by M H Barker. 1 The content of the thiocyanates in the blood is an index of the thiocyanate content of the tissues, and this depends on the intake and rate of excretion through the kidneys. 2 The rate of excretion of thiocyanates from the body is extremely variable. The only correlation is a tendency for the cyanate clearance to be depressed when the urea clearance is low (*THE JOURNAL*, March 25, 1939, p 1120).

Thus an important contraindication to the use of thiocyanates in vascular hypertension is seriously impaired renal function. The fatal outcome in the case reported by Russell and Stahl, in *THE JOURNAL*, August 8, in which thiocyanates were given in a patient with a urea clearance of 27, does not warrant their conclusion "that fatal intoxication may occur following the administration of the usually prescribed amount of the drug." The toxic effects are cumulative in the presence of impaired renal function.

At the hypertension and nephritis clinic of the Jewish Hospital of Brooklyn, we have acquired considerable experience with thiocyanate therapy in a large number of cases and have been favorably impressed with the results.

HARRY MANDELBAUM, M D, Brooklyn

To the Editor—The article by Russell and Stahl published in *THE JOURNAL*, August 8, does not keep a proper perspective toward the use of thiocyanates in the treatment of essential hypertension. The article failed to emphasize that a patient with hypertension and bad kidneys as evidenced by a urea clearance of 27 per cent of normal, nonprotein nitrogen of 43 mg per hundred cubic centimeters and 3 plus albuminuria was given the drug, contrary to accepted opinion that this is a dangerous type of case for the use of the drug. The article should also have emphasized even more strongly than the choice of improper case that the drug was continued in unchanged dosage after an excessively high blood level of 152 mg was found. The literature and experience indicate that, when a level above 10-12 mg occurs, toxicity is around the corner. There is no point in rounding this corner except for purposes of investigation. The choice of proper cases and dosage is similarly true in the use of many toxic drugs, such as digitalis, morphine and insulin.

Thousands of cases have been treated with the thiocyanates without fatality. My own experience also indicates that the determination of the blood concentration, its maintenance at proper levels, decrease of dosage when pronounced drop in blood pressure occurs, all will remove dangers of serious toxicity and

achieve the definite benefits of the drug in uncomplicated essential hypertension. Cardiac or renal failure or threats of failure are accepted contraindications for the use of the drug. Renal failure will cause the retention in the blood of any drug normally excreted through the kidneys.

Finally the diagnosis of hypertensive encephalopathy with uremia should at least be considered in this case as the cause of the initial onset. September 11 of headache, dizziness and mental confusion followed later by delusions, stupor, convulsions, coma and slow pulse. The relatively negative brain at post-mortem examination supports this thought. If this is true, venesection might have been tried rather than fluids intravenously.

Kentucky Reciprocity Report

The State Department of Health of Kentucky reports 6 physicians licensed to practice medicine by reciprocity and 1 physician so licensed by endorsement from January 21 through March 19. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Northwestern University Medical School		(1936)	Illinois
University of Illinois College of Medicine		(1920)	Illinois
St. Louis University School of Medicine		(1940)	Missouri
Washington University School of Medicine		(1937)	Missouri
Ohio State University College of Medicine		(1937)	Ohio
Medical College of Virginia		(1933)	Virginia
School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
Meharry Medical College		(1929)	U.S.P.H.S.

Oregon Reciprocity Report

The Oregon State Board of Medical Examiners reports 4 physicians licensed to practice medicine by reciprocity on April 7, 1942. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Columbia University College of Physicians and Surgeons		(1913)	N. Carolina
University of Oregon Medical School		(1937)	Maryland
Jefferson Medical College of Philadelphia		(1940)	Pennsylvania
Woman's Medical College of Pennsylvania		(1937)	New York

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals Electric Pad Burn Attributed to Negligence of Student Nurse—The plaintiff's complaint alleged that he became a patient in the defendant hospital for the purpose of obtaining treatment of his diseased right leg. His physicians decided to amputate the leg above the knee, and in order to prepare the plaintiff for the operation the administration of an opiate to induce a sound sleep was prescribed and an electric pad was directed to be placed on the leg above the knee to keep it warm and to maintain circulation. The pad used could be regulated to three degrees of heat, namely warm, medium and hot. The following morning it was discovered that the pad had been turned on to 'hot' rather than to 'warm' as directed and the skin, flesh and nerves of the plaintiff's leg above the knee had been seriously burned. Contending that such injuries were the result of defendants' having returned in its employ an incompetent, incapable and careless nurse, the plaintiff filed suit against the defendant hospital for damages and obtained a judgment in the trial court. The defendant then made a motion for a new trial, which was denied. From this adverse ruling the defendant appealed to the court of appeals of Georgia, division No. 2.

The defendant first contended that the trial court erred in overruling the special demurrer to the plaintiff's allegation that the defendant was negligent 'in allowing the plaintiff's leg to be burned and injured' as alleged. The court said that the plaintiff's complaint alleged that the servants of the defendant did not properly apply the electric pad to the leg, that in applying such pad they did not follow the instructions of the plaintiff's physician and that the employee who placed the pad on the leg was a student nurse, not properly trained. It was also alleged that the defendant, through its servants, was negligent in placing the pad on the plaintiff's leg in the high or hot position, which was a dangerous condition of the said pad unless carefully watched, in failing to inspect the pad after it was placed on the leg and in failing frequently to observe the pad and the plaintiff during the night. In these circumstances the court concluded the allegation that the defendant was negligent in allowing the plaintiff's leg to be burned and injured as alleged was not a conclusion and was not unsupported by sufficient allegations of fact. Such allegation did not place the defendant in the category of a 'guarantor' of the plaintiff against injury while a patient in the hospital.

The defendant then contended that the trial court erred in permitting a lay witness for the plaintiff to testify that she had had experience with electric pads, that she had herself used them on many occasions, that she knew of her own knowledge about a woman who used an electric pad on which the control switch was kept at the low position constantly for a period of three weeks and that such pad did not burn this woman at all within such period and that in her own experience she had never seen one of the pads burn anybody on low, but if the switch was placed in the high position it would burn the skin and flesh in half an hour or hour. The court pointed out that this witness was not testifying as an expert but was testifying as to her experience and of what she knew as the result of her experience. A nonexpert witness, the court said, may give an opinion as to the safety or danger of a particular appliance where, from familiarity with it or by reason of having seen it operated, the witness has gained a personal knowledge thereof.

Finally the defendant contended that the nurse who attended the plaintiff was carrying out the orders of the plaintiff's physicians and therefore was not at that time an agent or employee of the defendant hospital. The court said that the jury might well have found from the evidence that had the electric pad been placed on the plaintiff's leg as directed and had the attendants and nurses of the defendant hospital maintained the proper observation of the plaintiff and the electric pad during the night the leg would not have been burned. It is well settled, continued the court, that the owner or proprietor of a private

hospital or sanitarium which is operated for profit and not for charity is liable for injuries to patients due to the negligence of nurses or other employees. A private hospital operated for pecuniary profit owes to the patient the duty to use reasonable care for his safety and reasonable skill and diligence in nursing and caring for him. It is the duty of those in charge of the hospital, said the court, to give the patient reasonable care and attention, and to have that knowledge of the necessities of the case which would result from such care and attention and from the possession of ordinary skill in his treatment, the patient is generally admitted to such a hospital under an implied obligation that he should receive such reasonable care and attention for his safety as his condition may require. The court of appeals accordingly concluded that the evidence warranted the jury in finding for the plaintiff and that the trial judge did not err in overruling the defendant's motion for a new trial. The judgment for the plaintiff was accordingly affirmed—*Piedmont Hospital v Anderson*, 16 S E (2d) 90 (Ga., 1941).

Insurance Accidental Death Following Hypodermic Injection—The defendant insurance company agreed to pay double indemnity benefits if the insured died from bodily injuries effected through external, violent and accidental means and of which there was a visible contusion or wound on the exterior of the body, provided death did not result from disease. On the death of the insured, the beneficiary sought to recover the double indemnity benefits and the trial court entered a judgment dismissing her complaint at the close of her case. She accordingly appealed to the United States circuit court of appeals, second circuit.

The insured was 52 years of age at the time of his death and prior to July 3, 1939 had regularly enjoyed good health. During that day he had been drinking. Early in the evening a physician who called to see his invalid mother, finding her somewhat disturbed by his exhilaration, urged him to go to bed. On his request for a sedative, the physician administered to him a hypodermic injection of "a quarter of morphine and $\frac{1}{150}$ of atropine." The next morning his wife found him lying on his back in the same position in which he had been left the night before. He was unconscious and breathing irregularly, his pulse was extremely weak, his pupils were contracted and his face was almost black. He was given a stimulant and moved to a hospital, where he died fifteen days later from "putrid empyema" of the right side—a pulmonary infection caused by an attack of aspiration pneumonia. At the trial the plaintiff produced expert testimony to the effect that aspiration pneumonia may be contracted from nothing more than a drainage into the lungs of mucus and saliva, which ordinarily contain germs of the disease in infectious quantities, and that it is not dependent on a victim's peculiar susceptibility. Furthermore, such drainage will occur in one whose cough reflex is paralyzed, particularly while he is resting in a supine position. The insured's unconsciousness on the night of his intoxication fulfilled both of these conditions, and the evidence produced by the plaintiff was sufficient to warrant a jury in finding that the hypodermic injection was the sole proximate cause of his unconsciousness. The immediate cause of the insured's death admitted the court of appeals, was pneumonia, which would itself fall within the excluded category of "disease" rather than the protected category of "bodily injuries." The effects of the pneumonia, such as empyema, however, were unquestionably "internal injuries" and they, as well as the pneumonia itself, were merely intervening links in a direct chain of causation beginning with the hypodermic injection and ending with the insured's death. It has been held in similar circumstances, the court continued, that the event inducing the disease, not the disease itself, was the proximate cause. The hypodermic injection was an "external" and "violent" means within the meaning of the double indemnity clause. It clearly would have been an "accidental means" if it had led to a fatal blood poisoning. That it led to pneumonia instead seemed to the court to be entirely irrelevant to its accidental nature. In either instance the administration of the injection was intentional and deliberate but the result was unforeseen and undesired. Such miscarriage of a supposed remedy occurred in either case, not because the insured did, or submitted to, anything unintended at the time but because acts willingly performed bore unknown potentialities.

We think, concluded the court, that, on the proof offered the hypodermic injection could be found to have been the "accidental means" of the insured's fatal injuries and that a judgment of dismissal at the close of the plaintiff's evidence was improper. The judgment for the defendant was accordingly reversed and the cause remanded for further proceedings—*Simpson v Travelers Ins Co* 121 F (2d) 683 (1041).

Workmen's Compensation Acts Suicide from Brooding Over Pain of Industrial Injury Not Compensable—Suicide while insane, said the court of civil appeals of Texas Fort Worth, of a workman who had been injured in the course of his employment may be compensable under the Texas workmen's compensation act if the insanity results from a compensable accident and not from a brooding over the injury or other causes. Thus when there follows as a direct result of the accident an insanity of such violence as to cause the victim to take his own life through an uncontrollable impulse or in a delirium or frenzy without conscious volition to produce death, there is a direct and unbroken causal connection between the physical injury and the death. However, when the suicide is the result of voluntary and willful choice determined by a moderately intelligent mental power with knowledge of the purpose and effect of the act, even though dominated by a disordered mind a new and independent agency breaks the chain of causation. In the present case, the court denied compensation under the following facts. The employee suffered a painful foot injury from stepping on a nail or other sharp object. Excruciating pain persisted for about six months and the employee in his own words, "to get out of this pain," while, in the opinion of the court, sane and able to appreciate the consequences of his act and not while in "any state of excitement or delirium or frenzy," drank a mixture of concentrated lye, cleaning fluid and insect powder, from which he subsequently died. The undisputed evidence in this case, said the court, shows that the employee purposely and intentionally drank the poisonous solution, that he knew what he was doing and that he knew and intended that the fatal effects should follow. Even though the employee considered that his pain was unbearable and even though he was willing to depart this life in order to escape it still there can be no recovery under the Texas workmen's compensation act if the suicide was the result of voluntary and willful choice determined by a moderately intelligent mental power with knowledge of the purpose and effect of the act even though dominated by a disordered mind—*Troders and General Ins Co v Jones*, 160 S W (2d) 569 (Texas, 1942).

Optometrists Liability for Prescribing Improper Glasses—The plaintiff, a 10 year old boy, was taken to the defendant optometrist, who examined the boy's eyes and prescribed glasses. After wearing the glasses for several weeks the plaintiff returned to the defendant with the complaint that severe headaches, nausea and "deep-seated pain in his eyes" had developed. The defendant reexamined the boy's eyes, found that the glasses were in accordance with his previous prescription and advised him that in a short time the headaches and nausea would subside. After another week or ten days during which time the headaches and nausea continued, the plaintiff consulted an oculist for relief. In a subsequent suit for damages against the defendant optometrist, the plaintiff contended, among other things, that his eyesight had been permanently impaired because of the improper glasses which had been furnished to him. From a judgment in favor of the plaintiff in the trial court, the optometrist appealed to the court of appeals of Georgia, division No 2.

The defendant contended that there was not sufficient evidence to sustain the verdict of the jury. The court of appeals said that on the basis of the evidence introduced in the case the jury was authorized to find that the glasses prescribed by the defendant were not suited to the plaintiff's eyes, that they were not corrective, that they did not remedy the impaired vision and that as a result of wearing such glasses the plaintiff suffered headaches and nausea. The jury was also authorized to find that the defendant was negligent in his examination and treatment of the plaintiff's eyes and that if the defendant had properly examined and treated the plaintiff's eyes, and had fitted them with proper and suitable glasses, the impaired vision

would have been corrected and the plaintiff would not have suffered pain as a result of wearing the glasses. In these circumstances the court concluded that it could not say as a matter of law that the defendant was not negligent and that he did exercise proper care and skill in examining the plaintiff's eyes in prescribing the glasses and fitting them. The defendant should certainly exercise skill and care in the examination of a patient's eyes, held the court, and in the prescribing and fitting of glasses, and whether or not the facts of this case showed negligence on the part of the defendant in his examination and treatment of the plaintiff was for the jury. In determining what constitutes ordinary care and what constitutes negligence, the court also concluded, the jury would not be confined to the testimony of an optometrist as to what constitutes ordinary care and skill in the examination and treatment of a person's eyes, including the fitting of glasses. The court therefore found that there was sufficient evidence to support the jury's findings and that the trial court did not err in denying a new trial. Accordingly, the judgment in favor of the plaintiff was affirmed—*Kahn v Shaw*, 16 S E (2d) 99 (Ga 1941)

Autopsies Liability of Private Mortuary for Permitting Coroner's Physician to Perform Autopsy—A violent explosion occurred at the plaintiff's home and a policeman, hearing the noise, ran to the scene, broke into the house and found the deceased, plaintiff's husband, lying face down on the kitchen floor. There was a cut on his head, blood was coming from his ears, and there was an odor of gas in the house. The policeman carried the body outside and called the "inhalator squad," but the man was dead. No physician was in attendance when the deceased died, no one saw him die and no one knew how or when he died, the cause of the explosion or what exploded. At the plaintiff's direction the body was taken to the defendant mortuary to be prepared for burial. The coroner's physician, under instructions from the county attorney's special investigator, visited the mortuary, examined the body and found it necessary to perform an autopsy in order to ascertain the cause of death. After apparently being authorized by the special investigator, he performed the autopsy that same day, the cause of death being certified as inhalation of carbon monoxide gas. No coroner's jury was impaneled. There was no question, however, but that the autopsy was performed by the coroner's physician acting in his official capacity and that it was done in a decent and scientific manner. Subsequently the plaintiff commenced a suit for damages against the defendant mortuary for allowing the autopsy to be performed without her consent. From a judgment in favor of the plaintiff, the defendant appealed to the Supreme Court of Nebraska.

The plaintiff contended that she had the right to the possession of the dead body of her husband in the same condition it was in when death intervened, that an autopsy unauthorized by her, or by some other person having authority so to direct by law, is an invasion of her rights, and that a coroner may not order an autopsy except under the circumstances prescribed by statute and only after inquest. The Supreme Court traced the legislative history of the coroner's office in Nebraska and found that the duties of the historical office of coroner had been transferred to the county attorney, who is required to hold an inquest on the body of any person who might have died by unlawful means. The calling of a jury in such instances, however, was within the discretion of the county attorney and an investigation made by the county attorney, without the assistance of a jury, was not necessarily in contravention of law. An autopsy, continued the Supreme Court, is required and justified when necessary to determine that the cause of death of a human being did not involve unlawful means and when necessary to secure the information that will enable the county attorney fully to perform the duties enjoined on his office in reference thereto. It is in all respects a matter of public interest in which public safety is necessarily involved. Under these conditions, the county attorney may legally order an autopsy to be made when, in his judgment, that is the appropriate means of ascertaining the cause of death, and he may do so without consent of the family, for such power is incident to the county attorney's official duty. Jurisdiction to hold an inquest, continued the court, is conferred on a county attorney by the find-

ing and custody in his county of the body of a person who has apparently come to his death by violent, mysterious or unknown means. The Supreme Court therefore concluded that the county attorney had jurisdiction to hold an inquest in the present case without the intervention or assistance of a jury, that this decision as made by him was sustained by the facts within his knowledge at the time it was ordered and constituted a reasonable exercise of the powers of his office and that the acts of his statutory assistants in connection therewith were legally performed and required by the public policy of the state. Under such circumstances, the Supreme Court said, the defendant mortuary did not transgress the legal duties it owed the plaintiff, since the act of the coroner's physician was clearly within the authorization of law. Accordingly the judgment for the plaintiff was reversed and the cause dismissed—*Sturgeon v Crosby Mortuary, Inc* 299 N W 378 (Neb, 1941)

Privileged Communications Introduction of Death Certificate as Waiver of Privilege as to Attending Physician—The introduction in evidence, said the St Louis court of appeals (Missouri), by a beneficiary suing on a policy of insurance of the certificate of death of the insured, signed by the attending physician, waives the privilege arising from the confidential relation between the physician and his patient. Thereafter the attending physician may be required to testify with respect to information which he has required from the patient while attending him in a professional character, which information, except for the fact of waiver, the physician could not be compelled to disclose in court. Furthermore, by introducing the certificate of death in evidence the plaintiff beneficiary likewise waives the privilege with respect to statements made in appropriate hospital records by the physician who executed the death certificate. When several physicians have attended a patient at or about the same time and the patient calls one of them to testify as to what was then learned about his condition, he cannot object to the testimony of the others as to the same matter. And, concluded the court of appeals, we see no reason why this rule should not be applicable to the statements of physicians in hospital records—*Bouhigny v Metropolitan Life Ins Co*, 160 S W (2d) 474 (Mo, 1942)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Roentgen Manifestations of Adult Toxoplasmosis—Sante describes pulmonary roentgenographic lesions of 2 adult patients with toxoplasmosis reported by Pinkerton and Henderson. The early pulmonary manifestations present an appearance of acute pulmonary congestion with edema, accentuation of the hilar shadows with an increase in the size and number of the markings radiating outward from the hilum and a blotchy blurred appearance. At this stage the picture is similar to that of passive congestion with pulmonary edema but without cardiac enlargement. At a more advanced stage the picture changes. The markings radiating outward into the lungs are no longer the predominating features, they become overshadowed by the increasing interstitial infiltration and alveolar exudation. The composite picture is one of conglomerate areas of infiltration crowding on one another and giving the appearance of irregular blotchy consolidation. The site of greatest involvement seems to be the lower lobes. The roentgen picture at this stage might

be simulated by any of the atypical pneumonias or mycotic infections. Extreme pulmonary edema from any other cause might be mistaken for this condition. Toxoplasmosis, however, is more acute and the symptoms are more grave. Prostration is extreme and toward the end of the disease the fever is high and dyspnea and cyanosis are intense. Essentially the process seems to be an acute interstitial pneumonitis with associated pulmonary congestion and edema.

Toxoplasmic Encephalomyelitis—Cerebral calcification and internal hydrocephalus are prominent features in necropsies of infantile or congenital toxoplasmic encephalomyelitis. Dyke and his associates believed that its identification by roentgen examination might be helpful in clinical diagnosis. They examined 10 cases of this disease. In 4 the diagnosis was not made until necropsy, while in 6 it was made clinically. Diffuse intracerebral calcification is the most striking roentgen evidence of infantile or congenital cerebral toxoplasmosis. It usually occurs in small flecks, 2 mm in diameter, or in streaks particularly in the basal ganglia or thalamus. Intracerebral calcification was observed in 8 of 9 patients whose skulls were roentgenographed. There was evidence of increased intracranial pressure in 4 while 3 subjected to pneumoencephalography showed decided internal hydrocephalus. When multiple cerebral calcification is exhibited in infants and young children toxoplasmosis must be seriously considered. Pneumonitis may occur in 1 case. Toxoplasma was demonstrated at necropsy to be the cause of pulmonary inflammation.

Atelectasis Following Pneumonia in Children—During 1939 among the 135 patients with pneumonia examined in the department of roentgenology of the Infants' and the Children's Hospitals there were 26 instances of atelectasis. The ages of these 26 patients ranged from 3 weeks to 10 years. 10 months. 17 were less than 2 years of age. The duration of acute illness at the first roentgen examination varied from two days to two weeks. The average was five days. In addition to increased density of the involved lung Wyatt saw three other roentgen signs: (1) displacement of the heart and mediastinum toward the area of increased density in 9 patients, (2) displacement and curving of an interlobar septum toward the area of increased density in 24 patients and (3) close spacing of large bronchovascular markings to form a curvilinear triangle of increased density within a lobe in 6 patients. In some patients the atelectasis as seen in a lateral view roentgenogram provided an explanation for clinical symptoms which were not consistent with the apparent dense infiltration observed in the posteroanterior film, and in others it offered an explanation of symptoms which would otherwise have been interpreted as due to recurrent pneumonia. The treatment was symptomatic, accompanied by chemotherapy in 10 instances. Clinical recovery was uneventful, except that of 2 patients, in 1 of whom bronchoscopic aspiration was required while in the other empyema had developed. The atelectasis usually disappeared in one to two weeks. All such patients should be followed roentgenologically until clearing is complete because of the ever present possibility of foreign body or bronchiectasis.

Syphilitic Primary Optic Atrophy—From 1918 to 1940 Moore and his co-workers treated 250 cases of syphilitic primary optic atrophy at the Syphilis Clinic of the Johns Hopkins Hospital and in private practice. The relationship of early treatment to the development of the optic atrophy could be determined in 235 and only 3 (1.3 per cent) had received anything approach-

ing adequate therapy, only 32 (136 per cent) had received any arsphenamine, while 188 (80 per cent) had had no treatment. These data show that adequate treatment of early syphilis nearly completely protects against the development of optic atrophy. Primary optic atrophy occurred in at least 8 per cent of all patients with acquired neurosyphilis. The incidence was still higher in the neurosyphilitic Negro. No significant decrease in its relative incidence was evident during the last two decades. The cerebrospinal fluid was normal in nearly 7 per cent. Primary optic atrophy occurred more than twice as frequently in syphilitic tabes as in other types of neurosyphilis. It was rare in uncomplicated dementia paralytica. The only clinical manifestations in many patients were primary optic atrophy and pupillary changes. The therapeutic results, subjected to statistical analysis by the life table method estimated from anamnestic data and influenced by a multiplicity of extraneous factors, reveal that blindness occurred in 28 per cent of untreated patients within one year of onset of symptoms, in 50 per cent within two years and in almost 65 per cent within three years. Six years after onset 75 per cent were blind, and after twelve years less than 90 per cent were blind. Routine antisyphilitic treatment failed to alter significantly the spontaneous course of the untreated disease. Subdural therapy precipitated blindness in almost 10 per cent of patients. Only 9 per cent of patients given malaria therapy were blind at one year after onset of symptoms, 14 per cent at two years and 18 per cent at three years. Thereafter, up to fifteen years, no additional blindness ensued. It was estimated that to the 25 per cent of selected patients who would retain more than 10/200 vision ten years after onset of symptoms fever therapy added an additional 57 per cent. The optic atrophy was unilateral in only 4 per cent at the initial examination. The variation in the course of optic atrophy could not be accounted for by differences in treatment alone. At least one additional factor which determined the ultimate outcome was the type of field defect. The prognosis was less favorable in the presence of central or paracentral scotomas. Adhesive arachnoiditis was not found by Dandy in 3 patients at intracranial exploration. No beneficial or deleterious effect followed the operation.

Diagnosis of Venereal Lymphogranuloma—In evaluating the yolk sac virus antigen of venereal lymphogranuloma, Axelrod performed one hundred and fifty tests with it and the normal chick embryo control. Of the 151 patients with rectal stricture, syphilitic pregnant women with hyperglobulinemia, with or without hyperproteinemia, and with inguinal granuloma tested with the virus antigen, 34 gave positive and 20 doubtfully positive results. Approximately 10 per cent of the positive tests were pustular or vesicular reactions subsequently resulting in ulceration. The use of the normal chick embryo control in these 54 resulted in one positive and two doubtfully positive reactions. The tests of 36 patients with inguinal lymphadenitis were positive in 14, doubtfully positive in 8 and negative in 14. Tests performed on 26 patients with rectal stricture resulted in sixteen positive, seven doubtfully positive and three negative reactions. Of fifty tests performed on random ward patients two were positive, two doubtfully positive and forty-six negative. One patient giving a positive reaction had no history of venereal lymphogranuloma, another was a Negro who had had an inguinal bubo which had ruptured and drained spontaneously about ten years previously. Of the 2 patients showing doubtfully positive reactions, 1 had a history of a bubo which had ruptured and drained spontaneously many years before. Three of twenty-three tests performed on pregnant women under antisyphilitic treatment were positive, two were doubtfully positive and eighteen were negative. Two of the women with positive reactions and 1 with a doubtful reaction had rectal strictures of the inflammatory type. Four infants of the mothers with positive tests, when tested neonatally, had negative reactions. The results of the virus antigen are consistent with the history and/or the clinical signs in a high percentage of cases.

Anthiomaline for Venereal Lymphogranuloma—Shaffer used anthiomaline (lithium antimoniomothomolate) intramuscularly in a dosage of 0.12 to 0.3 Gm. in aqueous solution for the treatment of 33 patients with venereal lymphogranuloma. The injections were repeated two to three times a week for twelve

to twenty injections. The only important toxic effect and one which limits its dosage is antimony "rheumatism," an arthralgia and myalgia which appear several hours after injection and last for one to several days. This effect can always be minimized by reducing the dose. After an average of eighteen injections 8 patients were considered cured, 16 improved and 9 not benefited. Anthiomaline was not a completely satisfactory preparation for all forms of venereal lymphogranuloma, it was highly effective in inguinal adenitis. In the anogenital syndrome it was not curative, but it caused a temporary arrest or recession of the active disease process in most patients. Anthiomaline produced effects that were as satisfactory as those obtained with the sulfonamides, although the action of the latter appeared more rapid. However, the hazardous reactions that occasionally follow the sulfonamides are not seen with anthiomaline. The alternate or even the concomitant use of both preparations might be efficacious when either alone might fail.

Addison's Disease—Of the 64 patients with Addison's disease who have been under the observation of Thorn and his associates and of the 94 treated with synthetic desoxycorticosterone acetate by other physicians elsewhere during the last three years approximately 50 per cent have been rehabilitated. In this series 148 were treated by subcutaneous implantation of crystalline pellets. Tuberculosis appeared to be the etiologic factor of the adrenal cortical insufficiency in less than 50 per cent. Approximately 80 per cent were between 20 and 50 years of age, 56 per cent were males. The presenting symptoms were weakness and fatigability in 100 per cent, increasing pigmentation in 94 per cent and anorexia in 91 per cent. Approximately 90 per cent required 1 to 5 mg. daily of the substance in oil intramuscularly or 2 to 10 pellets (125 mg. each) implanted subcutaneously. The mortality rate during the average one and seven tenths years of therapy was 154 per cent. 46 per cent

of the deaths were due to infection and 29 per cent to cardiovascular disease. Of the authors' 64 patients, 48 were definitely improved and 56 per cent of the male patients were restored to full time employment. Abnormalities in carbohydrate metabolism were exhibited by 75 per cent, abnormal electrocardiograms by 60 per cent, abnormal electroencephalograms by 69 per cent, abnormalities in creatine metabolism by 69 per cent and reduced hippuric acid excretion by all. These abnormalities persisted despite continued therapy with desoxycorticosterone acetate. Overdosage phenomena were transient hypertension, transient edema, circulatory insufficiency, tendon and muscular contractions and transient peripheral motor paralysis. Practically all could be explained on the basis of excessive retention of sodium and chloride. Therefore, supplementary sodium chloride medication, if used at all, must be regulated carefully.

Primary Splenic Neutropenia—Wiseman and Doan report 5 cases of what they believe to be a heretofore unrecognized syndrome characterized by neutropenia and splenomegaly as a result of a pathologically altered function of the normal spleen. The 'common denominator' of all was profound granulopenia, panhyperplasia of the marrow and splenomegaly. Varying degrees and combinations of hemolytic anemia and thrombocytopenic purpura were encountered and coincidentally corrected, that is apparently permanently cured, by removal of all splenic tissue and the patients were restored to normal hemolytotoxic equilibrium. Although the syndrome may superficially resemble Banti's syndrome, Felty's syndrome, subleukemic myeloid leukemia, hypoplastic anemia, malignant neutropenia or certain types of chronic infection, it is a separate and distinct entity based solely on splenic dysfunction. In this respect primary splenic neutropenia is more closely related to congenital hemolytic icterus and essential thrombocytopenic purpura. The essential diagnostic criteria are the presence of an easily palpable nontender spleen, a severe neutropenic leukopenia with variable even though slight anemia, and thrombocytopenia and panhyperplasia including the myeloid elements without maturational arrest of pathologic alterations in the bone marrow. These criteria justify the therapeutic test of splenectomy.

Chronic Rheumatic Heart Disease—Juster tried to ascertain whether infection of the upper part of the respiratory tract initiated rheumatic activity or complicated a preexisting active process. To this end he observed 222 children 5 to 15 years of age for three years. Of the patients 85 per cent experienced a total of two hundred and sixteen upper respiratory infections. The seasonal incidence was similar to that observed in rheumatic and nonrheumatic subjects. There was a direct relationship between the seasonal incidence of such infection and rheumatic activity. The leukocyte curves of the patients after being separated into four groups, according to the classification of rheumatic activity, and studied in relation to upper respiratory infections showed that in the inactive group upper respiratory infections were not followed by leukocytosis, whereas in the group showing activity of first, second and third degree, when persistent leukocytosis followed upper respiratory infections, it was usually preceded by a leukocytosis of varying periods. This indicated the existence of a preexisting rheumatic activity. In many, particularly in those with second and third degree activity, the leukocytosis became definitely elevated within one to three weeks after the respiratory infection. A latent period was often mentioned prior to a recurrence. When this occurred, preexisting rheumatic activity was usually present. The data suggest that approximately 60 per cent more rheumatic activity exists in the subclinical form than is recognized by clinical manifestations of the disease.

Periarteritis Nodosa—More cases of periarteritis nodosa would be diagnosed, according to Banovitch and his co workers during life if the clinical pathologic changes were properly appreciated. They report 5 cases they have encountered at the Cumberland Hospital during the last two years. In 4 the diagnosis was made before death. The changes have as a common underlying process an arteritis. The following complications of arteritis are encountered: necrosis of a vessel wall with hemorrhage, thrombosis of arteries with hemorrhagic or anemic infarctions, aneurysmal dilatation of the arterial walls with secondary changes and replacement fibrosis of thrombi and tissues destroyed by the foregoing secondary changes. Varying degrees

of cirrhosis of the liver were present in all cases. The process most likely represented healed lesions of panarteritis. Lobular pneumonia, present in most of the cases, appeared to be a terminal event and without any special significance. Periarteritis nodosa is to be considered in any continued illness, and while the symptoms may be related to all the organs involved, no symptoms of the disease may be present. Of the 106 cases reported in the English literature antemortem diagnosis was made in 30 including the authors' 4. At times the diagnosis may be verified by biopsy of a subcutaneous nodule or muscle examination of a surgical specimen or laparotomy. In 1939 5 of 101 patients were known to be alive. A patient may survive if the disease remains localized in some organ such as the appendix or, if in a vital organ it progresses to the healed stage without producing functional insufficiency. All the authors' patients died. There is no specific treatment.

Androgens and Estrogens for Senile Pruritus—Feldman and his collaborators used estrogen and androgen for treating senile vulvovaginitis, leukoplakia and kraurosis vulvae and their accompanying pruritus in 16 patients. The first 12 who have been treated long enough for the results to be convincing have obtained uniformly good results; the other 4 will no doubt also have a completely favorable response. Several considerations impelled the authors to treat senile pruritus in the female with testosterone propionate and in the male with estrogens. To guard against error in estimating the authenticity of the effect of the endocrine substances on senile pruritus, several patients whose itching returned after an intermission in the endocrine medication were given injections of sesame oil or 1 per cent solution of procaine hydrochloride. During this control therapy the itching in each remained stationary or increased in intensity. This treatment of senile pruritus cannot be regarded as a cure. The method exerts a maintenance effect on persons with an endocrine deficiency. The length of treatment and the dose vary with each patient. 10 mg of testosterone propionate or 1 mg of estradiol dipropionate constitutes a safe dose. There is apparently no ill effect from the medication except for the local effect of estrogens on the female sex organs: uterine bleeding and painful nipples. This can be counteracted by combining an estrogen with an androgen (testosterone propionate).

Intensive Arsenotherapy of Early Syphilis—To date Schoch and Alexander have treated more than 350 patients with early syphilis by the intensive arsenotherapy. 208 were treated by the ten day syringe method which consists in giving 120 mg of mapharsen daily for ten consecutive days by rapid syringe injection. The remaining 142 patients were given smaller doses over a longer time. Hemorrhagic encephalitis was encountered three times. It resulted in 1 death. One hundred and three of the patients have been under close observation for six to eighteen months and in 77 per cent satisfactory results (the patients became clinically and serologically well) have been obtained. Results in 11 per cent are pending (the patients are

clinically well but residual reagin in the blood is still present at the time of writing) and in 12 per cent the treatment was a failure. The failures consist of 3 patients with infectious relapses, 1 with periorbitis, 6 with serologic relapses and 2 with positive serologic reactions of the spinal fluid.

Irradiation in Deafness—Emerson and his associates describe a simple and effective method of irradiating the eustachian orifices for deafness secondary to hypertrophy of lymphoid tissue which uses simple instruments and only 25 mg of radium. The procedure is within the reach of most clinics. One hundred patients with a history of deafness and eustachian adenopathy were treated with excellent results, some return of hearing or arrest of the process should be considered a good result, especially for a patient in the teens. Any preexisting infection of the upper respiratory tract should be eliminated. The type of deafness discussed is insidious in its onset and progress and can be detected only by the wide use of the audiometer.

Treatment of Poliomyelitis—The physiologist states that the passage of a muscle through its complete range of motion at frequent intervals enhances rather than retards recovery by stimulating the venous circulation and lymphatic passages to the affected members. During the 1940-1941 epidemic of poliomyelitis in Iowa Steindler and his associates studied 200 patients particularly from the standpoint of the development of contractures, which took place in approximately 25 per cent. Severe and persistent extension contractures usually developed in patients who had been maintained in splints for some time. Definite evidence of circulatory disturbances which result not only in impairment of circulation but in definite changes in the bone in the segmental area of the musculature involved are most definite in patients with the most severe involvement of the surrounding musculature and contracture. As early as two or three months after the onset of poliomyelitis there was a definite loosening of the ligamentous reinforcements of the severely involved joints, especially of the ankle and the shoulder. These changes occurred particularly in patients who had been wearing airplane splints and in whom a constant upward pressure on the shoulder joint was at work. From these observations it must be assumed not only that muscle is involved but that ligaments, bones and tendons play a part in the pathologic changes of anterior poliomyelitis. Extensive involvement of the musculature of the trunk was observed in more than half of the patients. It was difficult to correlate the contractures of single

groups of muscles because of the widespread and spotty nature of the paralysis. Since making these observations the authors have tried to overcome the condition at its inception. They remove the splint for an hour twice a day and let the patient lie on his side with his hips and knees flexed. This is apt to loosen the contracture of the back, and there is no evidence that it produces contractures of the knee or hip. Miss Kenny has emphasized the fact that the patient must be reeducated to the use of the individual muscle, her suggestions for individual muscle training have been adopted and certain departures from the old time orthodox treatment have been necessary. However, all fixation or immobilization should not be abandoned. Limbs that are unstable in their joints, whether or not they have recovered from the paralysis, must be supported. When walking or standing is resumed, such apparatus should not be used beyond the point at which static instability makes it necessary. When the soundness of the newer clinical observations in infantile paralysis is established, the application of common sense and of general biologic principles will free the treatment of poliomyelitis from orthodoxy and radicalism.

Respirators—McLoughlin points out that not all patients placed in respirators are cured or even helped. The apparatus is not the miracle wonder that it was hoped and still believed by many to be. Regardless of the cause of respiratory involvement, the respirator is indicated when the function of the intercostals and the diaphragm is impaired. The amount of help provided will depend on the nature of the functional impairment. When ever a patient with signs of impairment of respiration is seen every effort should be made to determine the cause, nature and extent of the impairment. If the difficulty is mainly with the intercostals and the diaphragm, he should be placed in a respirator. Too often the respirator is considered a last resort, and the patient is allowed to continue to use his weakened respiratory muscles until they have become exhausted, and collapse from fatigue results. As strength returns to the paralyzed and weakened muscles the patient must not be allowed to remain out of the respirator for too long intervals. The intermittent use of the respirator is often necessary for months. Patients with severe pharyngeal paralysis do very poorly in respirators and there is danger of aspiration of a plug of mucus which has accumulated around the glottis. Every physician should know the indications for and the value of the use of the respirator. The bulbar types of paralysis do not show satisfactory improvement, and they account for most of the disappointing results with the respirator.

Coup-Contrecoup Mechanism of Craniocerebral Injuries—Courville reviews 206 consecutive cases of fatal cerebral injury in which contusion of the brain was sustained while the head was in motion. Of the 202 in which the survival period

was known, death occurred on the first day in 69, on the second in 23, on the third in 20, on the fourth in 12, on the fifth and sixth in 7, on the seventh in 5, in the second week in 32 and after more than two weeks in 27. The common sites for cerebral contusion were the temporal lobe in 145 and the frontal lobe in 84. It seems clear to the author that a coup (direct) injury can be sustained in the right lower central area, while the contrecoup (indirect) injury to the brain can be apparently limited to the relatively quiescent minor temporal lobe or so diffused as to result in only minor and transitory reflex changes. This suggests that, even in the presence of minor injuries, coup as well as contrecoup injuries to the brain may occur and evidence of such injuries can often be found if looked for. A temporary loss of function of the right visual cortex may result from some disturbance due either to shock or to local circulatory changes consequent to the impact of the occipital region against a solid object. Coup effects do occur after falls on the back of the head, even though no grossly visible lesion results from them. These effects are transitory and due to functional rather than to structural changes. Microscopic alterations in transient contrecoup occipital cortex injury would be discovered if searched for. They would probably be vascular in origin, possibly on an anoxic basis (owing to local transitory disturbances in blood supply incident to commotio cerebri). In addition, some such injuries are produced by transmission of a wave of force (pressure) through the brain tissue.

Total Thyroidectomy for Heart Disease—From an analysis of the 362 instances of thyroidectomy performed for heart disease in 1937, a questionnaire sent to the persons and clinics supplying the data for the report and on their personal experience in 5 cases, Parsons and Purks conclude that total thyroidectomy is of negligible value in congestive heart failure. This might be expected, as any theory which would reasonably explain why improvement should occur is absent. On the other hand, it appears that certain carefully selected patients with angina pectoris may be and actually are benefited by the operation, also the procedure should be considered for patients who have not been benefited by medical measures.

Pseudomyxoma Peritonei in Man—Chaffee and LeGrand believe that their case of mucocoele of the appendix with pseudomyxoma peritonei in a male patient is the fifteenth of its kind. The clinical diagnosis, the pathologic picture and the surgical procedure were carefully considered. Although ovarian cystadenoma is the common source of pseudomyxoma peritonei, mucocoele of the appendix should not be overlooked. There are no reliable diagnostic clinical features for either. Peritoneoscopy aided the authors in the diagnosis of their case. Cecectomy including the dependent part of the cecum and the appendiceal attachment is a rational procedure. Appendectomy and post-operative irradiation are indicated for pseudomyxoma peritonei. The actual cause of the death of their patient twelve days after operation was a series of related events: perforation of the appendiceal stump, peritonitis and ileus. The patient would otherwise have died of compression of the bowel or the mesenteric vessels by the myxomatous material.

Pseudohypoparathyroidism—Albright and his collaborators report 3 instances of the clinical picture of hypoparathyroidism in each of which there was evidence of failure of the organism to respond to the hormone. The expression Seabright bantam syndrome derives its origin from the fact that the male Seabright bantam has female feathering, the cause of which is not that the testis produces female hormone but that its feathers respond in an abnormal way to the normal male hormone. Another probable example of failure of an end organ to respond normally is seen in patients with a low basal metabolic rate without any other evidence of hypothyroidism. They usually require more thyroid hormone to elevate their metabolism than is required by patients with true hypothyroidism. The inference is that the low metabolism is due to a failure of the body to react in a normal way to the hormone. Another human example is the absence of beard in the American Indian. The data of the 3 patients suggest strongly that the disturbance was not a lack of the hormone but a resistance to it. The evidence for this was the following: Abnormal serum calcium and phosphorus values failed to tend toward normal on large amounts of solution of parathyroid, 2 patients failed to show a phosphate diuresis following solution of parathyroid intravenously and 1 patient had a normal parathyroid tissue on surgical exploration. The cause for their peculiar physiognomy (round face and thick set figure) is obscure; it may be pure coincidence, but the authors feel that it is not.

Deterioration in Organic Epilepsy—Arrieff and Yacorzynski tested 27 outclinic epileptic patients at intervals of one to nine years with two to five Stanford Binet intelligence tests. For the group there was definite deterioration with an average decrease of six points between the first and last tests. The patients as a group differed from patients with nonorganic epilepsy in that their initial intelligence scores were lower. In 11 per cent there was a significant increase of the intelligence scores and in 37 per cent a decrease. Four of the patients who were tested more than twice showed a progressive trend toward deterioration.

Reversible Headache—Scott outlines a test which he has found of value in differentiating headache due to cerebral tumor, migraine, hypertension, meningitis, cerebrospinal syphilis, anxiety neurosis and malingering. Steady, firm pressure with the thumbs is made against both malar bones for ten seconds, when the patient is asked "Now, what has happened to your pain?" Following the patient's answer, the thumb pressure is suddenly released and the patient is again asked the same question. If the headache is irreversible, that is, of somatic source, the patient will answer that nothing has happened or that the headache is worse. However, in most instances when the headache is reversible, as in anxiety, hysteria or malingering, the patient will state that he had complete relief when the malar pressure was applied and a sudden return of the headache when the pressure was released. The same result occurs on repeated trials.

Tonsillectomy and Poliomyelitis—The fourteen years' experience in the relation of poliomyelitis to tonsillectomy at the Children's Hospital in Akron and of one year at the City Hospital of Cleveland is tabulated by Toomey and Krill. Seventeen of the 210 patients at the children's hospital died, as did 18 of the 220 at the city hospital. In 14, or 82 per cent, of 17 patients who had had a tonsillectomy or adenoidectomy within thirty days prior to the onset of poliomyelitis the bulbar

type of paralysis developed. Of 134 operated on prior to thirty days at both hospitals, 52 had bulbar poliomyelitis. At the children's hospital 8 of the 16 children with the bulbar type died. At the city hospital 8 of the 36 died. In 7, or 5 per cent, of 140 nonsurgical patients admitted to the children's hospital and 23, or 194 per cent, of 118 similar patients admitted to the city hospital, bulbar poliomyelitis developed. Here again most of those who died were in the bulbar group—5 of the total 7 at the children's hospital and the 9 at the city hospital. If only the mortality of the group that had spinal or nonparalytic poliomyelitis is considered, the rate seems insignificant—2 per cent at the children's hospital and zero at the city hospital. The many individuals who had had a tonsillectomy and an adenoidectomy within thirty days of bulbar poliomyelitis cannot be explained on the basis of mere chance or random sampling. In the regions discussed, it would appear to be advisable to do tonsillectomies in the late spring.

Treatment of Retained Placenta—Uterine inertia or atony is probably responsible for most instances of an adherent retained placenta. A less frequent cause is the so called constriction ring or hour-glass uterus. Most authorities agree that manual removal is indicated when the third stage is prolonged from one to two hours after delivery. Shannon states that in three and a half years ended June 30, 1940, 52 cases of retained placenta occurred among 7,776 total viable births at the Cincinnati General Hospital. Forty-three occurred in multiparas and 9 in primiparas. Manual extraction was used in 37. To avoid manual extraction with its high morbidity (37.8 per cent) and mortality (27 per cent) the other 15 were treated according to the method of Majon-Gabastou, by the injection of the umbilical vein with sterile saline solution through a modified intravenous apparatus. In 14 the placenta was expelled within thirty minutes, in 5 spontaneously and in 9 with slight to moderate suprapubic pressure. In 1 the method failed and manual removal was resorted to. A general uncorrected morbidity rate for the 15 was 7.1 per cent. There were no deaths in this series. The modified intravenous apparatus used consists of a Kelly bottle containing sterile saline solution, a rubber connecting tube, a three way stop cock, a 50 cc syringe and a no 18 short beveled intravenous needle. While an assistant steadies the cord, the umbilical vein is pierced and 250 to 400 cc of sterile isotonic solution of sodium chloride is quickly injected. As the fluid enters the placenta, the uterus is felt to rise up out of the abdomen. The cord is then clamped and the onset of the uterine contractions is waited for. Contractions were usually reestablished within fifteen minutes.

Respirator Dermatitis—Petro reports on facial dermatitis exhibited by 16 members of a Royal Navy depot at which weekly respirator drill was practiced. The lesions were confined to areas of the face which came in contact with the rubber. The symptoms became progressively worse following each drill. Masks from certain firms were responsible for the dermatitis, and patch tests with rubber disks cut from these respirators showed positive reactions. The diagnosis was confirmed by ascertaining the nature of all "accelerators" and "antioxidants" (two organic compounds) used in the manufacture of the masks. Rubber not treated with these substances gave negative patch tests at all times. Three to fifteen weekly fifteen minute exposures to potentially harmful masks were necessary for sensitization in predisposed subjects. Perspiration conditioned by temperature, humidity, exercise, diet and individual susceptibility proved an important predisposing factor, as the incidence was lower during a cold spell. The early symptoms were a mild burning sensation, an irritation of the areas in contact with the mask and/or transient erythema at the sites of irritation. Scratching was unavoidable and gave rise to pyogenic infection. The vesicular and weeping stages which followed were frequently associated with edema of the facial tissues, which gave an appearance of puffiness, double chin and aging. A protracted dry and scaly stage followed the subsidence of the acute inflammatory phase. With gradual desquamation the affected areas became smooth, but were discolored for a few days. The most effective prophylactic measure would be the recall of all potentially harmful masks and their replacement by innocuous varieties. Prompt treatment in the earliest stages ensured a rapid cure, and replacement of the incriminating respirator by an innocuous one prevented recurrence. The early stage of erythema responded to dusting with calamine powder.

or talc. The more pronounced erythema required calamine lotion or Burow's solution (a 25 per cent liquid aluminum acetate). In the later stages of vesiculation, weeping and crusting, calamine liniment was effective. In superadded pyogenic infection a 20 per cent sulfonamide paste cleared up the condition. The dry scaly stage responded to treatment with boric acid ointment followed by an ointment of 0.65 Gm of salicylic acid and 0.65 Gm of ammoniated mercury in 1 ounce (30 Gm) of soft petrolatum.

Universal Donor with High Titer Isoagglutinins.—Aubert and his associates determined the anti A and anti B isoagglutinin titers of 250 group O donors. In assessing the results of the transfusion of plasma or serum from these donors to 12 fully conscious group A recipients they paid particular attention to the clinical reaction of the recipient, the effect on the recipient's erythrocytes and the antiagglutinin mechanisms. Although symptoms possibly attributable to the action of these isoagglutinins developed in several of the recipients, no reactions were observed which caused more than a transient deterioration in their general condition. Even in the patient in whom severe lumbar pain, hemoglobinemia and hemoglobinuria developed the symptoms subsided in a few minutes except for a mild headache. The hemoglobinuria persisted for six hours, but there was no evidence of renal impairment. In 5 of the 12 moderate or severe aching pain across the small of the back often radiating to the thighs, constricting sensations in the neck and chest, intestinal colic and nausea developed. No conclusions can be drawn about the cause of the reactions. They may be due to unidentified substances in the serum. Rigors in 3 and headaches and pyrexial reactions above 100 F in 9 were also encountered. These are apt to occur with transfusions not involving incompatible isoagglutinins. A substantial rise in the serum bilirubin suggesting abnormal erythrocyte destruction occurred in 7 recipients, in 3 this was supported by a fall in the erythrocyte count. The remaining 5 recipients receiving high titer O serum or plasma (titer 512 or over) did not show either hemoglobinemia or intravascular agglutination, but large serum bilirubin rises were again found, suggesting that erythrocyte destruction had occurred. The serial blood counts of 1 of these patients revealed a drop of two million erythrocytes and a slight rise of bilirubin lasting for four days. The question of the titer at which erythrocyte damage in the recipient becomes substantial is of the greatest importance. The protection to the erythrocytes offered by appreciable amounts of plasma agglutinin in the recipient is not absolute. Therefore, when a transfusion is designed to raise the recipient's erythrocyte count, homologous group blood should be given if possible. In an emergency when restoration of the blood volume is the chief aim, the use of universal blood is justified. Plasma and serum may also be given for this purpose. When pooled in suitable proportions the anti A and anti B titers rarely exceed 16, the isoagglutinin content is small enough to be given with confidence to recipients of any group.

Sublingual Administration of Methyl Testosterone.—Spence states that the effectiveness of methyl testosterone administered sublingually to a eunuch was equal to or even greater than that obtained from intestinal absorption following oral therapy. Normal potency was maintained on two 5 mg tablets sublingually, but three such tablets were required for oral medication.

Miniature Mass Roentgenography in Royal Air Force.—Since November 1941, Trail states 19,969 men of the Royal Air Force have been examined by miniature roentgenography. The results of the study revealed 54 with active and 67 with inactive tuberculosis. Of the 54 with active tuberculosis, 24 were less than 20, 21 between 20 and 24, 4 between 25 and 29, 3 between 30 and 34 and 2 were 35 or more years of age. Of the 67 with inactive tuberculosis, 11, 24, 21, 10 and 1 were in the respective foregoing age groups. In addition, calcified nodules calcified lymph nodes or both were found in the films of 168 men. Total evidence of tuberculous infection was 145 per cent. The results of the study do not entitle one to a statement beyond the fact that almost all the miniature films showed pulmonary abnormalities in greater contrast to that seen on large films. This does not imply that every abnormality was detected. However it does mean that a number of pulmonary abnormalities, particularly pulmonary tuberculosis, have been discovered in individuals who, up to the time of taking the miniature film, complained of no symptoms and that their condition had not been discovered by the ordinary routine medical examination.

Sulfanilamide in Nasal Diphtheria.—Study of the nasal swabs of 388 diphtheria patients revealed to Boissard and Fry that hemolytic streptococci in the nose of these patients more than doubled their titer (eighty-seven and a half days) in the hospital and the diphtheria carrier period. The odds were 3 to 1 in favor of a child with two or less positive nasal swabs being discharged by the fifteenth day and 4 to 1 for one with more than two positive nasal swabs. The authors were so deeply impressed with the influence on the diphtheria of the concurrent streptococcal infection that they tried sulfanilamide intranasally in 26 children with a heavy double nasal infection who had been positive for four to twenty three weeks. In 24 the nasal infection was abruptly and permanently ended after eight days of treatment. In the other 2 this result was achieved by a second course. In addition, 2 nasal carriers with a double infection for eleven and five months respectively, were treated outside the hospital and cured. It is concluded that the persistence of *Corynebacterium diphtheriae* in the nose mainly depends on the associated hemolytic streptococcal infection, which can be cleared up with sulfanilamide powder. The results suggest that sulfanilamide also has a direct action on *C. diphtheriae*.

Blood Transfusion for Obstetric Hemorrhage and Shock.—From 1929 to 1940 transfusions were given at the Glasgow Royal Maternity Hospital to 765 women for obstetric hemorrhage and shock, 259 women died as a result of these conditions. The figures when subdivided into the necessary subgroups justify the provisional conclusion that the efficacy of blood transfusion for obstetric hemorrhage is well supported but that its value for obstetric shock is doubtful. When the twelve years are divided into periods of three years (during each of which transfusion was used more frequently and obstetric care became better) Sheehan points out that the data show that deaths from hemorrhage fell significantly in the last two periods. The hemorrhage-shock deaths show a slight decrease, but the shock-hemorrhage and the shock deaths do not show any fall. There is no evidence to show that blood transfusion was of any benefit in shock, whether complicated by moderate hemorrhage or not. There is little evidence that shock in obstetrics is fundamentally different from shock in surgical trauma. Until more objective evidence is available, it does not appear justifiable to assume that transfusion for shock in obstetrics gives information which is inapplicable to shock in other conditions.

Primary Tuberculous Infections in Adolescents and Adults—Leitner emphasizes that the primary infection of adolescents and adults is not as rare as was formerly believed. About one third of adolescents and young adults still give a negative tuberculin reaction. The course of the primary infection in adolescents and young adults is not more unfavorable than in children except when the infection results from massive numbers of bacilli or takes place over a long time. The primary infection is latent in the majority of cases, it may be recognized by the fact that the negative tuberculin reaction becomes positive. In a small number of cases the primary infection is accompanied by objective manifestations in spite of the absence of subjective complaints, the roentgenogram shows pulmonary infiltration or lymph node enlargement. In a third, still smaller, group the primary infection is manifested by both subjective and objective symptoms. The author's own observations were made on the last two groups. This report is concerned chiefly with the third group. Symptomatology and the clinical course of a manifest primary infection were studied in 28 cases. In the majority the condition began with a febrile period which lasted from two to four weeks or only a few days. Only 2 of the 28 patients had no rise in temperature. Catarrhal symptoms were frequent, 23 of the patients had a cough, but only 1 had expectoration. The physical findings were slight, the percussion note was shorter and the respiratory sound was altered over the area of infiltration, rales were not heard, as a rule. In the presence of enlargement of the hilus nodes a stenotic note due to the compression of the bronchus may be heard. Roentgenoscopy revealed pulmonary infiltration. Unilateral enlargement of the lymph nodes was characteristic. The erythrocyte sedimentation speed is usually accelerated during primary infection, but it rapidly returns to normal. The blood picture discloses a neutrophilic deviation to the left, frequently also a lymphopenia. Eosinophilia, which is indicative of the early appearance of allergy, was observed in 4 cases. The temperature, sedimentation rate, blood picture and serum coagulation reaction as well as the clinical picture resemble those of an acute infectious disease. The tuberculin reaction is strongly positive during the manifest primary reaction. The test became positive at the onset of the clinical signs, from four to six weeks after the infection. The Mantoux tuberculin reaction in the serum became positive later. Erythema nodosum was relatively frequent (11 of 28 cases) as an accompanying symptom. Microscopic examination of a nodule of erythema nodosum disclosed the allergic nature of the condition. Besides the typical course with regression of the primary infiltration and of the lymph node swelling within six months there were other manifestations of the primary infection. There was exudative pleurisy in 6 cases and polyserositis in 1, with Poncet's rheumatism and with generalized caseating tuberculosis of the lymphatic system. Cases with early intrapulmonary dissemination are of greater practical importance, they may imitate a phthisic evolution. The author obtained valuable information regarding the incipient pulmonary tuberculosis of adults. In spite of the fact that these types progress endogenically, superinfection is not ruled out, tuberculin positive persons may develop tuberculosis following a massive exogenous infection. If the primary infection is diagnosed early, prompt treatment can prevent an unfavorable development. Patients having an unclarified condition with pulmonary symptoms should not be placed in hospitals for tuberculosis. Tuberculin tests may clarify the diagnosis in some

cases. By keeping those with a negative reaction out of tuberculosis hospitals, not only will unnecessary expenses be avoided but infections will be prevented. The treatment of primary infection is conservative, but it should not be too short.

Mental Effects of Shock—Wespi experienced a mild shock following an explosion in which he sustained facial burns. The shock was mild enough so that he could observe on himself the physical and mental effects of the condition. The shock was evidenced by objective symptoms: dilatation of pupils in the presence of relative bradycardia and increase in blood pressure. Psychologically the shock produced a regression into primitive logical mechanisms. The psyche was split in two: besides the logical, causal reasoning of a scientifically trained person there suddenly appeared the illogical thinking of a primitive person at the level of animism. An object (stove) was personified, the unpleasant experience of the shooting out of the explosion flame was projected on an object in the form in which the psyche had experienced it. The object appeared animated. This produced an intolerable dissociation with the still existing causal reasoning. The consciousness became altered in a peculiar manner: one part was logical, the other part illogical, primitive, animistically projecting. Part of the consciousness regressed to an older form of thinking. The process of projection is the typical aspect of this animistic stage of reasoning: the psychic experience is seen in the object in the place of the own psyche and becomes indissolubly mixed with it. The object (stove) becomes a vehicle of a part of the psyche of the subject, it becomes animated for the subject. By the projection of parts of the psyche to the object, the subject's psyche becomes changed, the consciousness is reduced and the result is a state which Janet designated as "lowering of the mental level." The condition becomes intolerable when, besides the newly erupting mechanisms of primitive thinking, there remain causally reasoning parts of the consciousness, like islands of a broken up continent. Logical reasoning originating in these islands was incapable of overcoming the dissociation. Only the cathartic action of the appearance of the extreme pains restored coordinated causal reasoning. The author does not assert that this psychic mechanism occurs in every case of shock. It is probable that the intensity of shock determines the psychic depth to which the subject is reduced.

- *Blood Serum Phosphatases D Garcia Romeu L del Portillo and J H Piedra —p 121
Dacryocystostomy versus Dacryocystectomy T R Yarnes —p 132
*Shock V Banet —p 155

Blood Serum Phosphatases—Garcia Romeu and his collaborators studied the behavior of alkaline and acid phosphatases in the blood serum of 3 normal persons and of 32 patients. The figures for blood serum phosphatases in normal persons were the same as those previously reported in the literature. In the early stage of osteitis deformans, blood serum alkaline phosphatase was greatly increased while acid phosphatase was diminished. In the advanced stages of the disease both alkaline and acid phosphatases were increased. Blood serum alkaline phosphatase was diminished in pathologic fracture due to osteoporosis. It was increased in obstructive jaundice. Blood serum acid phosphatase was normal in chronic myeloid leukemia and in lymphoid leukemia, whereas it was increased in the hemato-cytoblastic and acute myeloid types of leukemia. The increase of acid phosphatase in acute myeloid leukemia is directly proportional to the number of immature cells and also to the number of total cells. In adenocarcinoma of the prostate with metastases, blood serum acid phosphatase was increased in a proportion to the extent of metastases. In view of the fact that the increase in acid phosphatase and the course of prostatic metastases may be controlled by castration or endocrine therapy the authors suggest that a similar effect control may be obtained in hemocytoblastic and acute myeloid leukemia.

Shock—Shock can be prevented in some cases, says Banet, by sparing the vasomotor system. Immediate administration of morphine, gentle transport of the wounded, prompt control of

hemorrhage in extensive wounds, immobilization of limbs in fractures and application of heat are the measures to be employed. Operations in the course of shock are hazardous. When they are indispensable, as when a bleeding vessel is to be ligated, the ligation should be gently performed under local or regional anesthesia. Causal therapy of the traumatized focus is inadvisable except when the traumatized tissues can be eliminated by a simple incision. Local anesthesia is to be preferred. If it is not available nitrous oxide or cyclopropane can be used. Chloroform or ether is contraindicated. Oxygen therapy maintains the wounded for a while. The following solutions are recommended for intravenous therapy: (1) the Medical Research Committee's formula, which consists of sodium chloride 20 Gm and potassium and calcium chlorides 5 Gm of each in 1,000 cc of water, (2) sodium chloride 8 Gm, sodium bicarbonate 15 Gm and sodium thiosulfate 4 Gm in 1,000 cc of water. Blood transfusion and blood plasma transfusion constitute the best therapy for shock. Plasma is indicated in pure traumatic shock and in shock due to grave burns, whereas blood transfusion is indicated in traumatic hemorrhagic shock. Intravenous injections of acacia solution are indicated when blood or plasma is not available. Intravenous injections of adrenal cortex extract are of value in preventing but is of relative value only in controlling shock. Effects of adrenal cortex extract are better when given after a parenteral introduction of isotonic solution of sodium chloride. Transfusion by way of bone marrow of blood or of isotonic solution of sodium chloride are indicated in shock due to grave burns, mutilation, diffuse edema, acute peripheral collapse, insufficient veins and during transport of the wounded. It is administered to adults through the sternum and to children through the lower end of the femur.

Demonstration of Transfused Erythrocytes in Blood of Recipient.—According to Krüpe, erythrocytes can best be identified by their serologic characteristics. The survival time of donor erythrocytes was estimated by Ashby in 1919 at between thirty and one hundred days. The author cites reasons why it is difficult to utilize the figures of the nonagglutinated erythrocytes as a basis for the survival of blood from O donors in recipients. The investigations on mixed blood with different factors have advantages over those on universal donor transfusions, because here the appearance and not the lack of agglutination reveals the presence of donor erythrocytes. In the course of studies on conserved blood, in which the problem was the transfusion of blood factors not matching those of the recipient, the author attempted to remove the donor erythrocytes from the blood of the recipient before he subjected them to serologic examination. He first clarified whether it is possible to remove from a mixture of erythrocytic suspensions of two different blood groups the erythrocytes that are present in lesser numbers. He also had to determine in what ratio of "donor" to "recipient" blood it is still possible to isolate an adequate quantity of donor erythrocytes. He found that 1. After storage of whole blood with dextrose citrate solution in the refrigerator, at temperatures of from +2 to +4 C, the M and N factors are demonstrable up to fifty-six days after withdrawal. 2. The erythrocytic factors M and N of group O blood that had been transfused after twenty-seven days of storage were still demonstrable in the blood of the recipient twenty days after transfusion. 3. On the basis of model experiments and of 9

cases in which blood transfusions were made, the author describes a method which makes it possible to isolate the donor erythrocytes from the blood of the recipient and then identify them on the basis of differences in blood groups and factors between the blood of the donor and the recipient.

Polysaccharides as Vehicles of Group Specific Properties in Man.—Kossjakow obtained from human erythrocytes of the A and B groups with the aid of a special method highly active group antigenic substances that were free from proteins, were soluble in water and were not soluble in alcohol, ether, chloroform and acetone. These substances belong to the group of the high molecular carbohydrates, the polysaccharides. They are thermostable toward temperatures of 100 C. They do not dialyze through collodion membranes, produce a positive molar reaction and show after hydrolysis reducing characteristics. The group polysaccharides obtained from human erythrocytes of groups A and B show a group antigenic action in experiments in vitro, but they exhibit no antibody forming capacity in vivo experiments and thus they belong to the category of haptens.

Development of Carcinoma on Basis of Condyloma Acuminatum.—Kramann reports the case of a woman aged 33 with a history of condylomas in the genital region for the past six years. The lesions were removed with a cold cautery and the resulting wounds healed with surprising rapidity. Since the woman refused a radical operation the ulcer was subjected to protracted roentgen irradiation which somewhat reduced its size. Several months later the ulcer increased rapidly and the woman died within several months. The necropsy disclosed a pavement cell carcinoma and necrotic metastases in the inguinal lymph nodes. The case is noteworthy because the condylomas, which generally disappear spontaneously after the forty-fifth year of life developed after that period. Moreover, they existed six years before the degeneration became evident.

Air Myelography for Diagnosis of Prolapse of Disk.—Busch prefers oxygen warmed to body temperature for roentgenography of intervertebral disks. A spinal puncture is made with the patient on the x-ray table with the pelvis elevated. From 40 to 50 cc of spinal fluid is fractionally replaced by oxygen, and more oxygen is introduced in order to obtain a slight excess pressure (from 250 to 300 mm of water). After the various roentgen exposures have been made, the excess

pressure is released by spinal puncture. Headache or vomiting may result if this is not done. For six hours after the examination the foot of the patient's bed is kept elevated. Serious complications were not observed. At first, roentgenograms are more difficult to interpret than those obtained with iodized oil, facility, however, is readily acquired. Diagnosis of median prolapse of the disk and of ligamentary compression of the root is usually accomplished without difficulty, the lateral prolapse of the disk is more difficult to detect. In such cases myelography with iodized oil may become necessary. These cases are exceptional, the author encountering only 1 in 50 verified cases of prolapse. The author performed air myelography in 64 verified and in some negative cases. He had used the iodized oil method in a slightly smaller number of cases. On the basis of his experience he prefers air myelography. The method is indicated (1) in patients with typical signs of prolapse, (2) in those with early signs of prolapse, (3) in those with lumbago sciatica and (4) in patients with relapsing sciatica.

Roentgen Diagnosis of Olfactory Meningioma—Erikson points out that Cushing introduced the term olfactory meningioma for tumors originating in the ethmoid plate. These tumors are often accompanied by skeletal changes, which Cushing regarded as secondary. He demonstrated that tumor cells penetrate into the canaliculi of the bone and thus produce an irritation that leads to the formation of new bone. According to Lysholm, meningiomas may present the following roentgenologic aspects: signs of increased intracranial pressure, shifting and calcification of the corpus pineale, calcifications of the tumor, vascular changes and local reactions. The last may be elicited by pressure atrophy and by destruction or new formation of bone substance. In the meningiomas that originate in the ethmoid plate the bone changes are not as pronounced as in other meningiomas. Cushing emphasized that skeletal changes may be missing even in comparatively large tumors. The author presents 14 cases of olfactory meningioma that were surgically treated at a Stockholm hospital. He describes the roentgenographic, ventriculographic and surgical observations. The roentgenographic characteristics were verified at operation. In 5 cases exostosis could be demonstrated in the typical position and appearance. Ventriculography permits an exact localizing diagnosis.

Roentgen Examination of Pancreas—Holm cites the difficulties encountered in the roentgenologic study of the pancreas. He distinguishes between direct and indirect pancreatic signs. The direct symptoms consist chiefly in pancreatic concretions and other calcifications inside the gland and partly in gas filled abscesses. The indirect signs develop when the pathologic process involves the surrounding organs and tissues. The author reviews results of 449 roentgen examinations of the pancreas. In 61 of these roentgenologic observations were verified at operation or by necropsy, in 26 neither operation nor necropsy revealed a pancreatic lesion, in 116 definite clinical signs of pancreatic disorders were present, in 104 viscera close to the pancreas were involved. The remaining 142 cases could not be classified with any of the other groups. In many there were symptoms suggestive of pancreatic disorders, but the results of the clinical examination were indefinite, while in many there were other diseases in which the behavior of the pancreas was not thoroughly investigated. The roentgenologic method used by the author is to be regarded as the study of the bed of the pancreas. He classifies the cases according to the size of the pancreatic bed. A normal pancreatic bed has about the same width as a vertebral body at the same level. The patients in whom the pancreatic bed was only three fourths or less of the vertebral width either had a chronic pancreatitis or were extremely emaciated. An enlargement of its size coexists not only with pancreatic disorders but also with obesity, ascites, tumors of the liver, metastases, infiltration due to perforated ulcers, hypernephroma and retroperitoneal tumors.

Epidural Contrast Investigation in Disk Prolapse—In about 20 cases in which clinical signs suggested a protrusion of a vertebral disk, Knutsson carried out roentgenologic studies

with epidural injection of perabrodil. Ten cc of a 1 per cent solution of procaine hydrochloride is injected and is followed by 20 cc of 35 per cent perabrodil. A protrusion big enough to cause occlusion of the epidural space with complete obstruction or a protrusion occupying the greater part of the cross section and thus causing a defect in the contrast shadow can be discovered. Smaller protrusions may not be discovered.

Terminal Ileitis and Its Roentgen Picture—According to Strombeck the lower ileum is equipped with abundant lymphatic tissue collected in Peyer's patches. The corresponding mesentery in the ileocecal angle contains similar accumulations of lymph nodes. Even under physiologic conditions this whole lymphatic apparatus is in a state of reaction toward the toxic and bacterial substances, which pass this region of great strategic importance immunologically and biologically. If this reaction exceeds a certain physiologic limit, symptoms of inflammation appear. The simple acute form of terminal ileitis is transitory in nature and may heal leaving no traces. Roentgenologically, the outline of the mucous membrane in the last 10 to 15 centimeters of the ileum is uneven and edematous. The mucosal swelling is most pronounced next to Bauhin's valve, the two lips of which are sometimes considerably swollen and bulge into the cecum. The mucous membrane relief in the end part of the ileum is high and irregular, and a walnut sized filling defect is seen at the site of Bauhin's valve. Roentgen examination can be of great value in differentiating acute appendicitis from acute simple terminal ileitis in children and young people. The earliest changes in chronic cases consist in disappearance of the transverse folds of mucous membrane and rigidity of the intestinal tube, as well as some constriction of the lumen. There are many cases of chronic terminal ileitis in which it is not possible clinically, roentgenologically or at operation to determine whether or not ileocecal tuberculosis is present. In none of the author's 7 cases of chronic terminal ileitis in which resection was done did the microscopic picture indicate typical tuberculosis. The author has evolved the following theory in an attempt to elucidate the various forms of terminal ileitis: 1. The ileocecal region, particularly the terminal ileum, constitutes an important part of the defense against various infections. Acute terminal ileitis must be regarded as a morphologic expression of this locally intense state of preparation. 2. Chronic inflammatory conditions of varying etiology can develop here. 3. An infection of the tuberculous type should have greater possibilities of healing (with fibrosis, and so on) in a region as active immunologically as this one than in other parts of the body. 4. Ileocecal tuberculosis is centered mainly in the cecum. Terminal ileitis can be produced by other agents than the tubercle bacillus, but there is reason to believe that tuberculosis plays a much more important part in the pathogenesis of the disorder than Crohn and others believe. The probability of tuberculosis increases the more the process is localized in the cecum and ascending colon. Acute ileitis has a characteristic roentgen picture, while chronic terminal ileitis presents a picture which cannot be differentiated from that of ileocecal tuberculosis.

Hygiea

Injuries to Ankle Joint. Review. I. Palmer—p 3167

Oscillometric Method in Diagnosis of Peripheral Arterial Disease—Christensen finds that oscillometric examination (1) allows diagnosis of slight degenerative changes in the arterial wall at a stage when arteriosclerosis cannot be established by palpation or roentgen examination, as plateau

ments were made with a planimeter. Results were inconclusive. The author realizes this as well as noting that a larger series of animals would be desirable for measuring the excretion of male sex hormones in impotent persons.

Finally the author discusses the social significance of impotence, cites legal authority regarding its place as grounds for annulment of marriage and makes a plea for further study of these cases.

Vascular Sclerosis with Special Reference to Arteriosclerosis. Pathology Pathogenesis Etiology Diagnosis Prognosis Treatment. By Fit Moshecowitz, A.B., M.D., Assistant Clinical Professor of Medicine, College of Physicians and Surgeons, Columbia University, New York. Cloth. Price \$3.75. Pp. 178, with 43 illustrations. New York, Toronto & London: Oxford University Press, 1942.

This monograph represents an integration and summary of the author's work on the subject during the past twenty-five years. A leading thought throughout the treatise is the mechanistic theory of arteriosclerosis. The author believes that normal intravascular pressure is an indispensable factor in the production of sclerosis. He does not deny the presence of other conditioning factors, such as the chemical composition of the blood, vascular supply of the walls of the vessels, intravascular stresses and perivascular resistance. But he maintains that the primary factor is intravascular pressure, which operates not only in arteries but in the entire vascular tree, such as veins, capillaries and the chambers of the heart. Normal or exaggerated function thus precedes morphologic changes, the reaction of the vessels to tension. Evidence is submitted that essential hypertension precedes arteriosclerosis and that arterio-capillary fibrosis in many visceral organs is the result of increased tension. The prophylaxis and treatment of arteriosclerosis lie therefore, in the treatment of hypertension which is briefly but adequately discussed. The author combines his long clinical experience with a thorough knowledge of the morbid histology of the vascular tree. If ever a problem required a correlation of the two points of view, arteriosclerosis is eminently one of these. The microscopic sections are excellent and so is the printing. There are only a few typographic errors. This is an important contribution, is stimulating and gives much food for thought. Its reading is strongly recommended to the general practitioner, who may detect the early changes and who may by adequate measures, slow the tempo of a disease, which at least anatomically, if not clinically, is an inevitable destiny of all vertebrates. Surgery of hypertension, while still in an experimental stage, is one of the hopeful approaches to the problem.

The Rat in Laboratory Investigation. By a Staff of Thirty Contributors. Edited by John Q. Criffith, Jr., M.D., Associate in Medicine, School of Medicine, University of Pennsylvania, Philadelphia, and Edmond J. Farris, Ph.D., Executive Director and Associate in Anatomy, Wistar Institute of Anatomy and Biology, Philadelphia. Cloth. Price \$7.50. Pp. 488, with 178 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1942.

This is a unique publication. The albino rat has come to be the most widely used laboratory animal since it is relatively inexpensive and is easy to breed, house and work with. Further, it has been well standardized, so that laboratory workers can compare their results with those of earlier workers in the field and with contemporary research in other laboratories.

The present volume is prepared primarily for those doing original investigative work. It should be of value also to students, technicians and those engaged in breeding rats. The clinician would find it of interest as a reference work on nutrition, psychologic phenomena and comparative anatomy. It might well serve as a reminder of the tremendous amount of exceedingly detailed work necessary in building a foundation in preparation for any laboratory scientific research program.

The book is exceedingly well edited, and the contributions of the thirty different authors fit nicely into a pattern without unnecessary duplication and without apparent contradictions. While it would be impossible to encompass all known knowledge about this one animal in one volume, a more complete picture would have been furnished if a chapter or two had been devoted to a more elaborate description of the uses and limits of use of the rat as a laboratory animal. There are excellent brief chapters on the use of the rat in the biologic assay of hormones and on dosage of drugs for rats but nothing on the use of

the rat in the study of bacterial and virus diseases of man. The chapter devoted to techniques for the investigation of psychologic phenomena in the rat, exhaustive and well prepared as it is, tends only to emphasize the need for a similar chapter dealing with the techniques for the investigation of communicable and infectious diseases. The chapters on anatomy, embryology, metabolism and hematology do, however, give a background for better use of the rat as an experimental animal.

The experiences of the more than thirty workers in thirteen universities, laboratories and institutions, combined as they are in this one volume, make a worthwhile contribution to the rapidly expanding works of research workers.

A bibliography accompanies most of the twenty-two chapters. In the more than eighteen hundred references a fairly complete reference list is supplied. For the most part these bibliographies do not include publications after 1939. Only six of the chapters cite references of 1940 and 1941.

Pain. By Thomas Lewis, M.D., F.R.S., Physician in Charge of Department of Clinical Research, University College Hospital, London. Cloth. Price \$3. Pp. 192, with 27 illustrations. New York: Macmillan Company, 1942.

This book is an up to date treatise on pain. It is written clearly and contains a tremendous amount of factual information based almost exclusively on work in the human being. It consists of fifteen chapters on pain sensitive tissues, the anatomic basis of pain types of pain, two systems of pain nerves in the skin, erythralgia, nociceptor tenderness, cutaneous tenderness and nerve injuries, pain and tenderness in ischemic muscle, excitants of pain nerves, referred pain, referred manifestations of somatic and visceral origin compared, pain of visceral disease, tenderness and rigidity in visceral disease, source of pain and associated reflexes in visceral disease and principles in the clinical use of pain. There is a good bibliography, although the author has omitted several convincing contributions discussing pain, the experimental work having been done on animals. This book should be in the hands of all neurologists, neurosurgeons, general surgeons, internists and neurophysiologists. It is highly recommended.

Hear! Hear! An Informal Guide to Public Speaking After Dinner on the Lecture Platform over the Radio. By William Freeman. Edited for America with additional chapters by Quincy Howe. Cloth. Price \$1.50. Pp. 180, with illustrations by Guyas Williams. New York: Simon & Schuster, 1941.

This book is just what its title says it is, a compendium of hints for speakers. Most men who have achieved success in various branches of trade or professional activity take it for granted that they are fully qualified to arise and address audiences on a variety of subjects without having given either the study or the practice to this art that they would give to any new modification in their own field. Nevertheless public speaking is both a profession and an art. Those who are trained in the field are invariably superior in the quality of their work, just as those trained in removing tonsils are superior to those who attempt that simple procedure without training. The chapter entitled 'How to Win an Argument' not only offers some practical hints but also some excellent anecdotes of modern debates. A special section is devoted to talking on the radio.

Hippocratic Medicine: Its Spirit and Method. By William Arthur Heidel. Cloth. Price \$2. Pp. 140. New York: Columbia University Press, 1941.

The name of Hippocrates is revered in scientific medicine not so much for any actual scientific discovery but for having established principles of thought which continued to guide medical science to our modern times. The eminent historian Heidel presents in this book a philosophic consideration of the Hippocratic contribution and of its evolution from the mysticism that preceded it. It is taken for granted that the Hippocratic writings are not the work of one person. The true significance of Hippocratic medicine, according to Heidel, 'lies in the circumstance that it is the expression of an age of incomparable importance in the intellectual life of the race.' It laid the foundations of modern science. Most important of all was the introduction of exact observation as the basis for medical practice.

SEA WATER ENEMAS

To the Editor—The question of sea water enemas discussed in *Queries and Minor Notes* in *The Journal* May 16, 1942, page 307, is a subject which holds considerable interest to any one in the naval medical corps and especially to those of us who are connected with aviation. The possibility of a forced landing at sea is always present and many of those so forced down have found themselves drifting far days in rubber rafts deprived of both food and water. Accordingly Lieutenant Pittard, one of the medical officers while at the School of Aviation Medicine at Pensacola, Fla., attempted some experimentation on the effects of rectal instillations of sea water with himself as the subject. The results were inconclusive but interesting and accordingly I am enclosing a copy of his report which appeared in *Contact* in February 1942. The latter publication is a local affair put out by the School of Aviation Medicine and sent to all those who at one time or another have attended the school.

Norman L. Yeod, M.D., San Francisco

Lieutenant M. C. U. S. Navy

ANSWER—The data presented by Lieutenant Pittard are not sufficient to support adequately his primary conclusion that is implied in the article's title, that dehydration can be relieved or prevented by the administration of sea water intrarectally.

Assuming that it is not attended by a concomitant loss of osmotically active substances (sodium or chloride ions) through vomiting, diarrhea or sweating, dehydration may be grossly described as a disturbance of the internal environment of the body that is characterized by a concentration of the ionic and molecular constituents of the intracellular and extracellular fluid compartments. Theoretically the only practical means of restoring the osmotic equilibrium of the dehydrated body is to provide it with a watery solution having a concentration of osmotically active nonoxidizable solutes lower than the maximal excretory capacity of the kidney for those substances.

Because the concentration of sodium chloride in sea water is close to 3 per cent (0.5 molar) and the maximal excretory capacity of the kidney for it is about 2 per cent (0.33 molar) (Davies, H. W., Haldane, J. B. S., and Peskett, G. L. *J. Physiol.* 56:444, 1922) a selective absorption of water from it by the rectum and colon, leaving the salt in the bowel, would be the only possible means that would enable the body to maintain its osmotic equilibrium (water balance) on sea water retention enemas.

Foy, Altmann and Koudi (*South African M. J.* 16:113 [March] 1942) have found that this theoretical mechanism is not operative in man. Urinary chlorides and blood chlorides rose to a much higher level in persons receiving sea water retention enemas than they did in those who had received nothing. They also noted a significant 'salt diuresis' and a greater loss of weight in the sea watered group. It was the opinion of the investigators that, although it is absorbed from the rectum, sea water does not alleviate or prevent the development of the subjective and objective signs of dehydration, that it is of little or no value in maintaining a normal water balance, and that it may actually be harmful in that it effects tissue dehydration rather than hydration and "causes maximal kidney work."

The latter data are sufficiently well controlled and show differences between the treated group and the controls that would justify a more strongly worded conclusion, which could be worded as follows: Sea water is absorbed from the rectum and colon, it intensifies tissue dehydration, imposes a maximal load on the kidneys, and does not prevent or alleviate the objective and subjective signs of a water deficiency.

ALOPECIA AREATA

To the Editor—A white girl aged 10 lost her hair completely two years ago. It then spontaneously returned for about one year. It is now disappearing once more. Can anything be done about this condition?

M. D. Ontario

ANSWER—This girl appears to have alopecia areata, which sometimes becomes generalized. It characteristically recurs after apparent cure, as in the case cited. Many theories have been advanced as to its cause but none of them can be proved. It often occurs in families whose nervous system is unstable. The attacks are often brought on by worry, fright, pain or other forms of nervous shock. It was discussed in answer to a query in these columns Sept. 28, 1935, page 1057.

Though it has received little attention for many years the theory of dental origin of this disease was revived recently by James D. Grace, D.D.S. (extensive Alopecia Areata of Dental Origin, *Arch. Dermat. & Syph.* 45:349 [Feb.] 1942). Of course the fact that the hair returned after correction of the tooth disturbance is no proof of such origin as Nobl points out. He treated a man with extensive alopecia of this kind for a long time with all the methods known (Nobl G. Ueber das Schicksal maligner Alopecien *Wien klin Wchenschr.* 48:205 [Feb. 15] 1935). Finally treatment was given up and after four years without any kind of therapy the hair suddenly began to grow and returned to normal. Nobl pointed out that it thus had occurred during treatment it might have been thought that a proof of etiology had been established depending on what form of therapy was being used at the time of the recovery.

Although the cause of the disease is not known there are methods of treatment that aid in recovery. This has been proved by applying the treatment to certain parts of the bald scalp and obtaining a more rapid growth of hair on the treated than on the untreated areas (Jackson, G. T. and McMurtry, C. W. *Diseases of the Hair*, Philadelphia: Lea & Febiger, 1912, p. 119). Such therapy consists of irritating applications to the bald areas at first mild, then stronger depending on the duration of the disease and the size of the area treated. Milder treatment is indicated for a recent attack and for large areas of baldness. Stronger ammonia water rubbed on several times a day after washing with hot water and soap is recommended early in the attack. If this has no effect after several weeks of use the physician may apply acetic acid once every fifth day. Cresolic acid in alcohol beginning with 30 per cent and increasing as the scalp becomes more resistant up to 90 per cent may be painted on the spots every five or seven days. Cutler's fluid (equal parts of tincture of iodine, chloral hydrate and phenol) may be used in the same way, or one part of phenol and four parts of lactic acid. Ultraviolet radiation strong enough to result in scaling increased at successive applications is valuable. In resistant cases, injections into the bald areas of one of the milk preparations is said to be effective. A preliminary injection of a minute amount of the preparation to guard against a possible sensitization is a wise precaution.

At each visit the physician should pull out loose hairs at the border of the diseased patch demonstrating the size of the area to be treated and showing the progress of the disease. In patients with low metabolic rate, thyroid is thought to aid in cure.

The prognosis in cases of universal alopecia is grave. A considerable percentage of these do not recover. However one never knows which ones these are so treatment should be given all. Children recover more often from the severe form than do adults. Recovery has been known to occur many years after the alopecia has become generalized.

SUBCUTANEOUS OXYGEN FOR RHEUMATIC DISORDERS

To the Editor—A physician recently demonstrated the following method of treatment for arthritis, lumbago and other painful conditions: Pure oxygen gas is injected into the tissues around the site of the pain with precaution taken to avoid getting the needle into a blood vessel. Is this a dangerous procedure? The doctor claims results where every other known treatment has failed.

M. D. Alabama

ANSWER—Therapeutic subcutaneous injection of oxygen is without serious danger if, as the questioner states, 'precautions are taken to avoid getting the needle into a blood vessel.' If the oxygen is given slowly the patient will experience little pain but he may note slight local soreness for a varying period of hours after the injection. One physician reported the occurrence of earache and of accidental inflation of the eyelids but these symptoms cleared as the gas was absorbed. In 1 case the oxygen was said to have caused temporary painful swallowing as a result of infiltration of the mediastinum during injections into the back.

The main threat of this procedure lies in the chance that the oxygen may find its way into a vein. Should this occur the intensity of symptoms will depend on the amount and speed with which the gas enters the blood stream. If a small amount is introduced there may be dry cough with transient dyspnea and some substernal soreness. It has been shown however that animals may be severely shocked and experience severe or even fatal convulsions if oxygen is introduced into veins quickly and in large amounts. Unquestionably the same thing could result in man.

This method of treatment for various rheumatic diseases has apparently found some favor in France but little attention has been paid to it in this country. The procedure has been recommended only in articles devoid of adequate case reports lacking

in control observations, and insufficiently documented with other objective data to permit independent judgment of the matter. No prominent rheumatism clinic in this country has seen fit to adopt this procedure, and its usefulness has not been demonstrated.

CONVULSIONS AND DEATH PROBABLY FROM COCAINE

To the Editor—A young man was being operated on for deviation of the nasal septum (submucous resection). He had been healthy all his life except for an occasional head cold and headache. The operation was to correct the defect so that he might enter the Naval Academy. About two months prior to the operation it was found that he had a bleeding time of twelve minutes and coagulation time of fifteen minutes. The blood and platelet counts were normal. After treatment with calcium gluconate, liver extract and thyroid the bleeding and coagulation time was brought down to three minutes each. The night prior to the operation he was given 3 grains (0.2 Gm.) of sodium amylal and this was repeated at about 11 o'clock next morning with morphine sulfate $\frac{1}{4}$ grain (0.016 Gm.) and atropine sulfate 1/150 grain (0.0004 Gm.) about forty-five minutes prior to the operation. About one-half hour prior to the operation his nose was sprayed with 2 per cent cocaine hydrochloride and irrigated with isotonic solution of sodium chloride. The mucous membrane was wiped with cotton soaked in epinephrine and 10 per cent cocaine hydrochloride following this the nose was packed with gauze soaked in cocaine hydrochloride 10 per cent. The operation was started about one-half hour later. About 0.25 cc. of 1 per cent procaine hydrochloride was injected into the septal mucosa but this was discarded as the cocaine anesthesia seemed sufficient. After about thirty minutes of operation (the cartilage had been freed on both sides and no trauma had been caused) the patient developed a slight pallor which was followed by cyanosis. Immediately prior to this he had been talking and feeling fine. He then had convulsive seizures of the hands and face which gradually spread over the body. He became unconscious and very cyanotic. Respirations were slow and jerky. The pulse was normal at first but later began to increase rapidly. In spite of oxygen and carbon dioxide caffeine with sodium benzoate, nikethamide and epinephrine intravenously the patient died. The pallor, cyanosis and convulsions seemed to develop suddenly after they started and respiration ceased ten minutes after the attack developed. This all occurred about forty-five minutes after the cocaine was given. A thorough autopsy revealed no pathologic changes of significance except a small amount of insufflated blood in the lungs thought to be the result of artificial respiration and bleeding from the nose. No hemorrhage was noted in the brain tissue. My opinion is that this was a respiratory death due to the cocaine hydrochloride. Previously he had had his nose sprayed several times with 2 per cent cocaine without any effect. Please give an opinion of the case.

MD U S Navy

ANSWER—Under the circumstances described it seems logical to ascribe the cause of death to toxicity caused by the administration of cocaine.

Susceptibility to the toxic effects of the so called local anesthetic drugs is known to vary widely among individuals and even in the same individual at different times. Whether a condition causing prolonged bleeding and clotting time or whether the administration of large amounts of either calcium gluconate, liver or thyroid might modify such susceptibility is not known. Apart from susceptibility the quantity of drug carried at one time by the circulation to the central nervous system is thought to determine the advent of "a reaction." The strength of the solution of cocaine used plus the vascularity of the surface to which it is applied probably influence the rapidity of entrance of the drug into the circulating blood. The latter factor (vasculature) is considered justification for the use of epinephrine to produce local ischemia. In the case cited it is possible that as the ischemia from epinephrine disappeared absorption of cocaine was rapid. The interval between packing and the onset of signs of toxicity is thus explained. The technique of applying anesthetic agents and vasoconstrictors is not uniform in present day practice. Whatever the method used, the possibility of disastrous results is always present.

Toxic reactions are usually first manifest by cortical stimulation. This may be evident for instance as talkativeness, tremor and slight twitching of the small muscles of the face followed by convulsions. Disturbances of the autonomic nervous system are usually evident. Depression of the vital functions of respiration and circulation is the terminal picture and cause of death. If a convulsion has preceded the depression, respiratory exchange is embarrassed or prevented during the attack, thus leaving the tissues with little or no oxygen at the advent of depression from drug action.

Logical treatment of a reaction from cocaine toxicity may then be divided into two efforts.

1. Immediate and early support of the respiratory function. This means the instant initiation of artificial respiration with oxygen as soon as possible. The use of pure oxygen and a mask and strong rubber breathing bag, pressure on which can force oxygen into the lungs, is ideal. When such simple equipment is not immediately available direct inflation of the patient's lungs from those of the physician or manual maneuvers must suffice. The important thing is to assure the presence of oxygen in the alveoli while there is yet circulating blood to carry it to the tissues. Considerable pressure or an artificial airway may

be necessary to accomplish respiratory exchange. Verification of lung inflation by observation of movement of the chest wall is helpful. The injection of stimulant or analeptic drugs is not usually considered of value.

2. Arrest of the convulsion. Abundant oxygen in the tissues probably acts as an anticonvulsant. However, when the convulsion has begun it can be stopped by the intravenous administration of a derivative of barbituric acid such as amylal, soluble pentobarbital or pentothal. Interruption or delay of artificial respiration with oxygen to prepare and administer the barbiturate is not justifiable. This should be accomplished by an assistant.

If adequate delivery of oxygen to the tissues can be maintained throughout the period of the reaction detoxification of the drug is usually rapid and recovery prompt and complete.

TREATMENT FOR PINWORMS

To the Editor—Can you give me any information on the gentian violet treatment for pinworms? Is it considered the method of choice? I have a child aged 3½ who refuses to swallow the enteric coated pills. Could I pulverize uncoated pills and give them to her in solution?

MD Maine

ANSWER—The gentian violet (methylosaniline) treatment for pinworms is the method of choice from the standpoint of safety and efficiency. The dose of the drug for adults consists in the administration of two 32 mg tablets before meals three times a day. This treatment is continued for eight days, the patient is then permitted to rest for a week following which the treatment is repeated for an additional period of eight days. Children may be given the drug at a dose rate of 10 mg daily for each year of apparent (not chronological) age, which is equivalent approximately to 32 mg ($\frac{1}{2}$ grain) a day for each three years of apparent age. This daily dosage should be divided into two or three parts. The period of treatment is the same as for adults. About one-third of experimentally treated patients suffered some reaction in the form of nausea, vomiting, diarrhea, abdominal pain, and the like. These symptoms can usually be controlled by reducing the dose or suspending treatment for a day or two until the patient returns to normal. In any event the full course of treatment should be given for best results. Contraindications for the use of gentian violet include concomitant infections with *Ascaris lumbricoides*, moderate to severe cardiac, hepatic or renal disease, alcohol and diseases of the gastrointestinal tract. Gentian violet is not well adapted for children too young to swallow tablets. Administration of the drug in solution is objectionable from the standpoint of staining the skin and mucous membranes. If given in this manner, it is probable that the efficiency would be somewhat reduced and that there would be a greater tendency to nausea and vomiting. Enema treatments may be used as an alternative in young children. High soapsuds or saline enemas are of value if repeated every other night for three to four weeks. However, hexylresorcinol enemas give better results. The child is given a high soapsuds enema at bedtime. Following evacuation of the fluid, a suitable amount of a 1:2000 solution of hexylresorcinol in water is administered by rectum. This should be retained as long as possible. This treatment should be given every other night for at least three weeks. In some cases more prolonged treatment is required. Repeated treatment over a period of time is necessary to allow for desiccation of pinworm ova in the patient's surroundings, otherwise reinfection is very apt to result. For the same reason it is advisable to treat all infected members of the family at the same time in order to eliminate simultaneously all household carriers. There is no treatment which will cure all cases, and persistence is often required in combating the infection. A few individuals show idiosyncrasy to hexylresorcinol and may suffer local reactions. The drug should not be administered to such persons.

OOPHORITIS FROM MUMPS

To the Editor—A single woman aged 25 had mumps three and one-half months ago. Soon after that pain started over both ovaries and has persisted ever since. It does not seem to cease. I have had her on bed rest. Pelvic examination shows some tenderness in both adnexal regions but there is no enlargement. There is no fever or discharge. Her periods are normal. What can I do to get rid of this pain?

Bernard Potmos MD Adrian Mich

ANSWER—Mumps often results in inflammation of the ovaries. After the illness is over there is no specific remedy for the oophoritis. Hence the customary treatment for inflammation of the pelvic organs should be used, namely, prolonged hot douches, hot sitz baths, diathermy and treatment with the Elliott or Newman machine. In addition the patient should rest as much as possible and should be given mild anodynes until the pain subsides.

FUNCTIONAL BOWEL DISTRESS

To the Editor—A man aged 28 who formerly suffered from infantile paralysis complains of severe flatulence which gives him considerable disadvantage during office work. I have treated with albumin tannate and a preparation of bile. They gave him some relief. The analysis of the feces showed only that meat was partially digested. Formerly he was treated with colonic irrigation without noticeable results. What else can be done for him?

M D New York

ANSWER—Before the diagnosis of functional bowel distress is made, the physician must be sure that the symptoms are not due to some organic condition of the gastrointestinal tract which has been overlooked. Protozoal infection of the bowel, specific food sensitivity and cardiovascular disease are other causes of flatulence which must be kept in mind. The presence of partially digested muscle fibers in the feces is not significant. However, the distress appears to be of functional origin, and it is unlikely that it is in any way related to the previous history of infantile paralysis.

It is suggested that this patient be given a low residue diet, consisting essentially of the elimination of raw fruits and vegetables, as well as beans, cabbage and other notoriously "gassy" foods. Candy, honey, syrups, bran, nuts, carbonated beverages, beer and spiced and highly seasoned foods should be avoided. Excessive smoking and chewing gum may also produce flatulence and should be forbidden.

Cathartics, especially saline laxatives, should be avoided, they may aggravate the flatulence. Constipation can be treated by dietary management, i.e., by including in the diet sufficient cooked fruits and vegetables to produce firm formed stools. Small oil or water enemas or glycerin suppositories may be employed occasionally if the patient is unable to expel the stool from the rectum. This can be determined by digital examination.

It is advisable to administer a mild sedative such as phenobarbital $\frac{1}{2}$ grain (0.03 Gm) three times daily, and also at night to promote longer hours of restful sleep. Tincture of belladonna in doses of 30 to 45 minims (2 to 3 cc) daily may also be helpful.

For the effective therapy of such functional conditions the physician must also recognize and evaluate the social and psychic factors present. Psychotherapy directed toward the alleviation of emotional or social problems may be an essential part of the treatment and on occasion may be the sine qua non of adequate therapy.

INTRAPERITONEAL CHEMOTHERAPY

To the Editor—The use of sulfanilamide and sulfathiazole powder in the presence of acute gangrenous appendicitis and purulent peritonitis and on the cervical stump in supra-cervical hysterectomy and sewed into compound fracture wounds has received wide attention and commendation in a large number of articles appearing in the medical literature. There seems to have been an increasing number of adverse reactions including slough of the appendix base with resultant hemorrhage and various foreign body reactions of the sulfanilamide powder. I have used sulfanilamide powder in the appendiceal stump region in the peritoneal cavity and in the incised wound at closure. The results so far have been encouraging but with the increasing evidence against its use I would greatly appreciate an opinion as to its advisability.

Paul B. Shuey M.D., Long Island City N.Y.

ANSWER—Chemotherapy has been used locally in the peritoneum for two indications: (1) to combat infection already present and (2) to prevent infection in a contaminated area.

In the presence of exudate and necrotic tissue, absorption of the chemical is slow and the local bacteriostatic effect is lessened. Sulfanilamide has no pronounced irritative effect on the peritoneum and does not excite a foreign body reaction. Sulfathiazole is not as readily absorbed and may remain as a foreign body to cause foreign body reaction. Absorption of the chemical is usually rapid, causing a peak of concentration within three hours in the absence of exudate and disappearance by the end of twenty-four hours. The concentration in the portal blood is much higher than that in the systemic circulation (Jackson and Collier *THE JOURNAL*, Jan 17, 1942, p 194) and hepatitis with jaundice may supervene. Enormous doses should not be used in the uninfected peritoneum, as around an anastomosis. It is probable that 5 Gm or less will do everything necessary under these circumstances. It is unlikely that sloughing, hemorrhage or other unfavorable local result is due to anything but the surgical pathologic process rather than to sulfanilamide. The general reaction, particularly hepatitis, is to be more feared. With the knowledge now available it is wiser to limit local chemotherapy in the peritoneum to sulfanilamide. In doses of not over 10 Gm in a field covered with exudate and not over 5 Gm in a normal peritoneum no harm is to be anticipated, certainly none due to local irritation.

NEURAL COMPLICATIONS OF PERNICIOUS ANEMIA

—CATARACT AND PERNICIOUS ANEMIA

To the Editor—A white man aged 46 is suffering from a combined sclerosis with comparatively minor changes in the blood picture. The diagnosis was established in one of the leading hospitals in this country. The anemia is completely controlled under intensive liver therapy (up to 60 units of crude liver a week). In addition to this the patient receives high doses of nicotinic acid and B complex. After eight months of treatment the neurologic condition is practically unchanged. Could you suggest any additional therapy? Somebody advised blood transfusions in spite of the now normal blood picture. I cannot conceive what blood transfusions could do in this case. What is your opinion? This patient offers another problem. He has a cataract in one eye which is now mature. The other eye is perfect. Two ophthalmologists whom he consulted gave opposite advice. The first advised operation, the completely controlled pernicious anemia is no contraindication. On the other hand there may be a loss of vision as the result of secondary glaucoma or other complications if the cataract becomes hypermature. He does not want to risk the loss of vision in the eye with the cataract because there is always the possibility that something may happen to the other eye. The other ophthalmologist is absolutely against operation. His reasons are that (1) the pernicious anemia is a contraindication and (2) he never operates on a cataract if the other eye is intact. What is your advice?

Benedict Nagler M.D. Newark N.J.

ANSWER—The patient undoubtedly has pernicious anemia with irreparable neural damage. There is no additional therapy that would be beneficial in such a case. Progression of cord damage can be prevented, however, if adequate liver therapy is continued. There is no reason to believe that blood transfusions would help this patient.

As to the cataract, the adequately controlled pernicious anemia with combined sclerosis is no contraindication to operation. Most ophthalmologists would choose to operate at the present time.

SCLEROSING SOLUTIONS AND SYNCOPE

To the Editor—I have observed 3 cases of syncope following injection of internal hemorrhoids. In 1 case the reaction followed immediately after the injection of Sylnasol and the blood pressure went to 40 systolic and 30 diastolic. In the others the reaction occurred in one half hour and in one hour. In all cases there was local pain followed by faintness, pallor, cold sweat and nausea. There had been several previous injections. As I have not seen any references to the complications in these cases I wondered what the mechanism might be.

M.D. Massachusetts

ANSWER—Syncope following the injection of a sclerosing solution may be due to one of two mechanisms. One should consider a sensitization to the injected drug, especially if there have been previous injections. Sylnasol is a proprietary solution which contains the sodium salts of the fatty acids of psyllium seed. Epinephrine 1,000 in doses of 0.3 to 0.5 cc given subcutaneously, may be life saving. But the syncope may also be due to a pulmonary embolism, in which case the thrombus caused by the irritating solution promptly breaks loose and is capable of producing identical symptoms. Dyspnea might be more pronounced in the allergic reaction but is naturally an important symptom of pulmonary embolism. Atropine $\frac{1}{4}$ grain (0.001 Gm), given intravenously, should be tried in the second form. It is doubtful whether a differentiation between the two types of reactions is always possible although edema and urticaria or chest findings and hemoptysis would settle the question. The bronchial spasm present in both forms may yield to intravenous administration of aminophylline.

ROENTGEN THERAPY FOR TUBERCULOUS
LYMPHADENITIS

To the Editor—A woman aged 25 has a large mass at the angle of the jaw involving the posterior cervical lymph nodes suspected of being tuberculous. Can you tell me the present status of roentgen therapy in tuberculous glands? How does it compare with surgical results? Any further suggestions would be appreciated.

M.D. New York

ANSWER—Assuming that the mass at the angle of the jaw in the case referred to is made up of enlarged lymph nodes, and assuming that the inflammatory process responsible for the enlarged nodes is tuberculous in character, roentgen treatment should have a favorable effect if the treatment is given properly. Not only the nodes visibly affected should be included in the field of irradiation but the entire side of the neck (or both sides if there is any evidence of lymphadenitis on the other side). The treatment should consist of a dose of approximately two thirds or three fourths of the so called tolerance or erythema dose and this should be repeated every three or four weeks for from three to six months at least. Rays generated at moderate voltage (between 130 and 140 kilovolts) and filtered through 4 mm of aluminum appear to give the best results in most cases.

Tuberculous processes in general frequently respond well to roentgen treatment, but the response is characteristically slow and treatment has to be repeated at the intervals mentioned. Occasionally, when one or more nodes have broken down and contain purulent material, it may be advisable to incise just enough to allow free drainage and then continue with roentgen treatment. Extensive excision of tuberculous nodes is seldom necessary or advisable.

As for comparing the results obtained by surgical treatment and by roentgen treatment, the effect of the former is more rapid but the cosmetic result is frequently more or less unsightly. Roentgen treatment usually brings the tuberculous process under control if the treatment is continued long enough, and the cosmetic result is far superior, but it requires more time.

DURATION OF CARBON MONOXIDE IN BLOOD

To the Editor—Please inform me as to about how long carbon monoxide may be found in the blood after having been present in sufficient quantities to cause coma. I have recently seen a patient thought to have carbon monoxide poisoning. He was unconscious for about thirty minutes. After this he awoke and because of pains in the chest and head was given $\frac{1}{2}$ grain (0.02 Gm.) of pantopon. He lapsed into a coma again and remained unconscious for seventeen hours. A blood sample taken nine hours after onset and while the patient was still unconscious did not reveal the presence of any carbon monoxide. He had had no other medication except oxygen by nasal catheter for several hours. Would all traces of carbon monoxide be likely to have disappeared from the blood at this time? The coma is still unexplained and the patient does not seem to be greatly affected by his experience.

Willard Cardwell, M.D., Greensboro, N.C.

ANSWER—The rate of carbon monoxide elimination is distinctly influenced by a number of factors, so that the duration of retention of appreciable quantities of this gas varies greatly. Under conditions of adequate respiratory stimulation the rate of dissociation roughly may drop one half every hour. Thus, if the blood saturation at the time of removal from the dangerous gas was 60 per cent under suitable treatment this might approximate 30 per cent at the end of one hour, 15 per cent at the end of two hours, and so on. The last 10 per cent of gas dissociates itself much less freely than is true for a given 10 per cent in higher brackets. Under ordinary conditions of questionable treatment the rate of dissociation may be slower and under some circumstances as much as an hour might be required to obtain a drop from 35 per cent to 25 per cent of blood saturation. The finding of low percentages of blood saturation from carbon monoxide is not extraordinary sixteen hours after removal from exposure. Conversely, the failure to detect carbon monoxide at the end of that period, or much shorter periods associated with adequate treatment, is not remarkable. The laboratory procedures commonly used in the measurement of blood saturation with carbon monoxide are not so accurate as to yield indubitable results at such levels as 2 or 4 per cent. Failure to detect carbon monoxide at the end of nine hours, and particularly after oxygen therapy, by no means rules out the possibility of carbon monoxide poisoning nor does the fact that a period of consciousness occurred between two periods of coma eliminate this possibility. Although it is not certain that carbon monoxide poisoning did exist, this becomes readily possible if any proof exists as to the presence of carbon monoxide in dangerous quantities in the air inhaled.

CONGENITAL SYPHILIS

To the Editor—An infant aged 3 months had a positive Wassermann reaction at 1 month and again at 3 months. At both times a Kohn reaction was negative, the cord was positive at birth. The mother's infection occurred between the second month when it was negative and the fifth month when it was found positive. She was treated with both mapharsen and a bismuth compound receiving both at most of the weekly visits up to confinement. Should one start treatment for syphilis in the infant? There have been no symptoms or clinical evidence of the disease found and the infant is doing perfectly well. A rather poor roentgenogram of the long bones at 1 month showed no abnormality. M.D. Montana.

ANSWER—The cord blood Wassermann reaction is worthless. In the first place it may simply reflect the mother's serologic reaction on the blood, under which conditions one would expect the serologic reaction to become negative in a matter of six weeks to two months.

In this case, in which the mother had syphilis that was contracted between the second month and the fifth month and has been receiving treatment since then, the situation is somewhat different, and since the child's serologic reaction is still positive at three months the child should be regarded as having congenital syphilis and started on treatment at once.

REPEATED INJECTIONS OF STROPHANTHIN FOR ANGINA

To the Editor—I would appreciate an opinion on what good can be expected when injecting intravenously strophanthin 0.025 mg. once a day for one week and three times a week thereafter in a case of coronary occlusion with myocardial damage of five years duration. Is there a possibility of decreasing the anginal attacks?

Ignatius Kornblüh, M.D., New York.

ANSWER—There would be a possibility of decreasing the number of anginal attacks suffered by a patient if the cardiac output could be increased by this method of treatment. Ordinarily strophanthin is given intravenously for its quick action, and one does not ordinarily continue the use of this drug daily thereafter. The other preparations of digitalis and squill which have similar action can be taken by mouth after the therapeutic effect has been achieved by some of the quicker acting drugs like strophanthin and cinobufagin. It might be wise to try having the patient wear an elastic abdominal support. If the patient is not too obese one of the light weight latex models may suffice but if the patient is obese with a pendulous abdomen a stronger elastic supporting belt, which can be obtained from many of the surgical supply houses, would probably be most effective. These belts should be tight enough so that they assist in the movement of the diaphragm during respiration, thereby increasing the amount of blood brought back to the heart.

CHRONIC GONORRHEA

To the Editor—About eight months ago a man aged 23 had an attack of gonorrhea which presumably was cleared up. About two months ago he broke loose with either another acute attack or a recurrence of the old condition. I put him on a course of sulfathiazole to no avail. After an interim I put him on a course of sulfapyridine. This lessened the discharge (merely an occasional drop at the external meatus) but the smear still was positive. Then I went back to sulfathiazole plus a course of gonorrheal vaccine. The smears are still positive. Would there be any point in trying any of the other sulfonamide derivatives such as sulfanilamide or sulfadiazine? If not, what would be your suggestion as to what to try next? I would sincerely appreciate any suggestions you may have to offer.

M.D., New York.

ANSWER—In view of the chronicity and continued urethral discharge one must look for a focus of infection in the prostate, the urethra or the paraurethral glands.

It is suggested that the patient have a course of prostatic massages and urethral soundings followed by instillation of a mild urethral antiseptic. These may be alternated with the treatments being given twice a week. It would also be helpful to have him instill himself once or twice a day with an antiseptic. Five per cent neosilvol is excellent and also does not discolor the clothes.

A course of sulfathiazole or sulfapyridine may be given with the treatment suggested.

MILK FARMS FOR REDUCING

To the Editor—Inquiries have come to my office asking where milk farms are located in Illinois for the purpose of exercise and reducing. Are these places approved by the medical profession?

Nora B. Brandenburg, M.D., Chicago.

ANSWER—In general institutions such as milk farms established for the purpose of exercise and reducing are not approved by the medical profession. Many of these institutions are conducted without proper medical supervision. Dieting is frequently too stringent, and unbalanced meals are often ingested over a sufficiently long period to lead to dietary deficiencies. Furthermore, after following this type of regimen, on return to former activities, the faulty habits of eating which originally produced obesity are usually resumed, and the weight lost is rapidly regained.

A list of the locations of such milk farms is not available.

SPECIFIC GRAVITY OF PROCAINE HYDROCHLORIDE IN SPINAL FLUID

To the Editor—What is the specific gravity of procaine hydrochloride dissolved in spinal fluid? Is it heavier than the spinal fluid or lighter than the spinal fluid?

Edwin M. Meek, M.D., Huntington, W. Va.

ANSWER—It is heavier than spinal fluid unless some material has been added for the purpose of making it lighter.

The Journal of the American Medical Association

Published Under the Auspices of the Board of Trustees

SEPTEMBER 19, 1942

THE EDUCATIONAL OBJECTIVES OF THE AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

CHAIRMAN'S ADDRESS

WALTER T. DANNREUTHER, M.D.
NEW YORK

Twelve years ago the Section on Obstetrics and Gynecology of the American Medical Association cooperated with the American Association of Obstetricians, Gynecologists and Abdominal Surgeons and the American Gynecological Society to create and incorporate the American Board of Obstetrics and Gynecology. It therefore seems logical to assay the accomplishments of the board and discuss briefly its original objectives, which have not been modified since its organization in 1930. Each of the sponsoring societies was and still is represented by three elected members, who are also directors and examiners. There have been five changes in personnel during the past five years, all due to resignations. The large number of candidates since 1936 has made it necessary for the nine board members to enlist the services of several associate examiners for the oral and pathologic examinations. These were wisely provided for in the articles of incorporation, and thus far only those holding professorial appointments in medical schools have been invited to serve in this capacity. The members of the board believe that this arrangement has many desirable effects. It has broadened and freshened their own points of view as examiners, familiarized several of the leaders of our specialty with the intimate details of the board's procedures and decisions, and emphasized a sincere desire to insure fairness to all candidates.

It was with the intent of directing and improving, but not controlling, the practice of obstetrics and gynecology by specialists that the board was originated, and there never has been any inclination to limit in any way the professional responsibilities that any licensed practitioner may care to assume. Its primary purposes were to encourage the study, improve the practice and advance the cause of obstetrics and gynecology, to induce potential specialists to prepare themselves thoroughly, to determine the relative competence of specialists in accordance with certain minimum standards and to grant and issue certificates of special knowledge in obstetrics and gynecology to those who voluntarily comply with

the board's requirements, without purporting to confer any legal qualification, license or privilege.

Certain fundamental policies were adopted in the beginning and have been continued ever since. The board has always desired to keep the application fee as low as possible without jeopardizing its finances. After nine years of operation a growing budget, in spite of strict economy, made it imperative to increase the fee for the first time. The board has expected its certified specialists to refrain from making excursions into other fields of practice, on the logical premise that the expert practice of a specialty after thorough training cannot consistently be combined with comparative mediocrity in other branches of medicine. The license to practice medicine is a legal certificate of general competence, and those who do incidental obstetrics and gynecology require no further testimony of their ability. On the other hand, when a practitioner presumes to designate himself as a specialist in a particular subdivision of medicine, his pronouncement carries with it an implication of superior training, extraordinary skill and a background of extensive clinical experience attainments which should be regarded as qualifying him to assume the responsibility for major obstetric and gynecologic problems, as well as to serve as an adviser and consultant to those of less experience. A specialist differs from other physicians in the character of his postgraduate training and practice not in professional ability. The board has consistently refused to lower its requirements of eligibility, so that in its certificate the public, both lay and medical, might have a reliable criterion whereby those who are really well qualified can be distinguished from pseudospecialists. The board has strictly confined its activities to its own business and has repeatedly declined to sponsor support or engage in other enterprises, regardless of their merit.

The board's examination includes a survey of the candidate's ethics and professional career, with particular reference to his special training and postgraduate work, estimation of the extent of his clinical experience, an inquiry into his obstetric and surgical judgment as disclosed by the character of his case records and an oral quiz, a determination of his familiarity with important contributions to the literature, a test of his knowledge of the essentials of the basic sciences pertaining to the clinical aspect of obstetrics and gynecology, especially pathology, both gross and microscopic, a review of his general knowledge and utilization of modern diagnostic measures and therapeutic resources, and a summary of his capabilities and adaptability in general. The board has always arranged for the review of written papers and case records, as well as the conduct of the pathologic and oral examinations by examiners remote from

the district in which a candidate practices, thus eliminating possible prejudice or favoritism.

Since 1930 the board has examined 1,770 applicants, of whom 1,457 passed and 313, or 17 per cent, failed. Another smaller group has never passed the written test or submitted satisfactory case histories. One hundred and eighty-nine formal applications for examination have been rejected as ineligible after a careful scrutiny by the committee on credentials. The total number of specialists certified to date, including 255 who were originally certified without examination, is 1,712. This is a fair index of the profession's appreciation of the value of certification, as applications have never been solicited.

There can be little doubt that the principles on which the board functions have promoted the unification, or at least the correlation, of obstetrics and gynecology in medical schools and hospitals during the past twelve years, so that a larger percentage of potential specialists have been exposed to fundamental training in both subjects. Many preexisting residencies have been lengthened and additional ones have been established, but the clinical material is still being wasted in some hospitals and the available opportunities are far from sufficient to supply the demand. Until the residencies are further amplified in both number and scope, it will be necessary in some instances for the board to accept postgraduate apprenticeship and clinical experience under satisfactory supervision in lieu of part of the required three years of institutional training in obstetrics and gynecology. The board's Committee on Graduate Education has done much to stimulate institutions to rectify some of these defects in our graduate educational system.

It is quite evident that most prospective applicants have become aware of the necessity for constant study and thorough preparation before presenting themselves for examination. They learn to read at home, visit other clinics and take postgraduate courses, thus forming habits which are likely to persist throughout their professional lives. The chief mistake made by those who are unsuccessful is the assumption that experienced clinicians will not be expected to know anything at all about the correlated basic sciences or that younger men who have spent several consecutive years in institutions can entirely substitute ultrascientific knowledge for clinical judgment. It is for that reason that the oral examination includes an appraisal of the extent of a candidate's knowledge, the character of his practices and his cultural and scientific attributes. Some applicants appear so nervous that they find it impossible to express themselves despite a deliberate effort on the part of the examiners to dissipate apprehension, and a few underserved failures have probably been due to this cause. Familiarity with the fundamentals of pelvic anatomy, physiology, biochemistry and especially pathology is an essential factor in the solution of antepartum, preoperative and postoperative problems. There is no requirement that candidates have formal graduate instruction in the basic sciences. All that is expected is a reasonable degree of knowledge of these subjects as related to the intelligent practice of obstetrics and gynecology. Conversely, scientific data cannot completely replace clinical experience in dealing with diagnostic and therapeutic problems. Hearing that the patient's temperature is 104 or the pulse 140 is quite different from telling it to some one else who must make crucial decisions. The board has recently encountered so many relatively young men who had devoted all of the next five years after the completion of a rotating internship to obstetric and

gynecologic internships, residencies and fellowships, and who had never carried the responsibility for private patients of their own, that it was deemed wise to increase the required years of practice from five to seven. With out a reasonable time spent in private practice, a candidate's integrity and ability as a private practitioner cannot be determined. It does not seem unduly exacting to expect one who professes to be an expert in certain disease conditions to be familiar with the intrinsic pathologic alterations in the tissues involved, but, until the board began to function, clinical pathology was practically ignored by many of those who had the greatest opportunity to profit by it. As a result of the stressing of gross and microscopic pathology in the examinations, it is probable that the specialists certified by the American Board of Obstetrics and Gynecology know as much pathology pertaining to their specialty as any other clinical group in this country.

Sometimes a senior obstetrician or gynecologist regards the failure of one of his staff as a reflection on his clinic or as an error on the part of the board. That mistakes may have been made can be freely admitted, but every effort has been made to avoid them. In event of a failure at least six examiners report orally on the candidate to the entire group of examiners and assistant examiners, reciting in detail the questions asked and the candidate's replies. It is therefore impossible that any one can be failed solely because of peculiar questions, a single question or a difference of opinion. Due respect is accorded each individual's methods of practice, and he may even deviate from accepted methods, provided he can justify such procedures by a reasonable argument. After a general consideration of all the details of the examination including a review of each candidate's records, capability and general adaptability, the applicants are passed or failed solely by a vote of the entire board. Assistant examiners express their opinions freely but have no vote. As a matter of fact, relatively few candidates who have failed have complained of injustice or resented the board's action as unfair, and the majority have apparently devoted a year or two to improving their qualifications and then passed a reexamination without difficulty. Most of the critical comments concerning those who have failed are made by some one other than the candidates themselves.

Whereas each specialty board has some problems peculiar to itself, there are certain other questions arising from time to time which are more or less common to all. So in 1933 the Advisory Board for Medical Specialties was organized to provide a forum for the discussion of matters of mutual interest and the coordination of certain activities. Contrary to the impression prevailing in some quarters the Advisory Board has no jurisdictional control over the certifying boards, most of which, like the American Board of Obstetrics and Gynecology, are legally incorporated. The boards which insist on restriction of practice to a specialty and otherwise require evidence of superior qualifications have occasionally been criticized for adopting standards which are regarded by some as unduly exacting. If requirements are not maintained at a high level, the operations of the boards would be merely intellectual exercise and certification meaningless. At any rate, the fact that approximately seventeen hundred obstetricians and gynecologists have not found it impossible to comply with the regulations of your board is testimony that its standards are not unreasonable. It has also been intimated that the boards may degenerate into

autocratic guilds because many institutions attach considerable importance to certification. It seems quite logical that hospitals, medical schools and special societies should evaluate for themselves the significance of certification and utilize it as they choose. Whatever formal action has been taken by such groups has been entirely spontaneous and has originated outside the boards. In fact, it seems impossible to conceive of how dogmatic decisions by the boards could be enforced on others, even if they had such an intent, which they have not.

Pressure is still being exerted to influence the board to relax its insistence on absolute limitations of practice to obstetrics and gynecology, particularly for the benefit of a minority of semispecialists in small communities who find it impossible to derive sufficient remuneration from strict specialization. If a field of practice is so small that this contention is valid, the practitioner of obstetrics and gynecology does not need a certificate of identification, for the lay inhabitants and other physicians in the vicinity are well aware of the relative qualifications of those who are particularly interested in one of the specialties and will attend to the proper distribution of patients. Any one especially competent in such an environment is soon appreciated and has little competition. If the time should ever come when for other reasons admission to the examinations would depend solely on excellence of training and competence, regardless of strict limitation of practice, it is certain that the graduate educational qualifications of those candidates would be even more closely scrutinized and the requirements of the board more rigidly enforced than they are at the present time. Such a radical alteration in the board's policy could be anticipated only if it should be conclusively demonstrated that the welfare of the smaller communities demanded it. In larger cities it is much more difficult to determine the true qualifications of those who claim to be specialists, and, while lack of certification by no means should be interpreted as evidence of nonqualification, certification does carry with it a reasonable assurance of competence as a specialist. The medical profession now has available for reference the Directory of Medical Specialists, which includes the biographic data of approximately eighteen thousand certified specialists in all branches of medicine.

The primary objectives of all the national specialty examining boards are not legislative or restrictive but educational and constructive. I believe that it may fairly be said that the constructive influence of the Board of Obstetrics and Gynecology has been manifested by the recent tendency of more medical schools and hospitals to unify or at least correlate, obstetrics and gynecology, by the realization of aspirants for certification that they must prepare themselves thoroughly for the practice of the specialty, by fostering the establishment of more and better residencies, by encouraging the compilation of better obstetric and gynecological records, by expecting recent ex-residents to acquire sufficient clinical experience before seeking recognition as specialists, and by the stimulation of clinicians to familiarize themselves with obstetric and gynecologic pathology. Nothing but the merit of its objectives and its successful accomplishments have been responsible for the momentum developed by your board, and nothing but these can perpetuate and insure its future existence.

EXPERIMENTAL FIBROIDS AND THE ANTIFIBROMATOGENIC ACTION OF STEROID HORMONES

ALEXANDER LIPSCHÜTZ M.D.

Director of the Department of Experimental Medicine National Health Service of the Republic of Chile

SANTIAGO, CHILE

Not being a gynecologist or an obstetrician I feel obliged to offer my apologies for presenting a paper on experimental fibroids and their prevention in this section inspired by practical aims which might be of use to suffering womanhood. Let me express my apology in the words of a great American. Almost one hundred and fifty years ago, a few days before the final treaty of independence with England was signed, Franklin saw in Paris the first balloon ascension. The spectators argued about the utility of the

Fig 1—Uterine tumors induced in the guinea pig by estrogens. A, enormous subserous and parametric tumoral masses on the dorsal face of the uterus fifty one injections of 80 mg of estradiol monobenzoate in the course of four months. B, pedunculated tumor and apical tumor of the mesosalpinx same treatment. C, subserous tumors induced by subcutaneously implanted pellet of estrone. Absorption was of 11 mg daily in the course of four months.

experiment. What good, some skeptic asked, could a balloon be? What good, Franklin replied, was a newborn baby?

Obstetricians and gynecologists will be the first to appreciate or not the claims of the scientific newborn babies which experimental fibroids and antifibromatogenic steroids are.

Subserous uterine fibroids were first elicited in the United States by W. O. Nelson in a number of guinea pigs subjected to prolonged treatment with estrogens.

Read before the Section on Obstetrics and Gynecology at the Ninety Third Annual Session of the American Medical Association Atlantic City, N. J. June 10, 1942.

This work has been aided by the Jane Coffin Childs Memorial Fund for Medical Research, the Rockefeller Foundation and others and has been realized in 1937 to 1942 in collaboration with Drs. R. Iglesias, L. Vargas, O. Koref, P. Bellolio, R. Murillo, F. Rodriguez, A. Jedlicky, J. Chaume, I. Szabo, E. Egaña, S. Bruzzone, J. Palma, R. Thibaut, C. Nunez, O. Vera, J. Zañartu, S. Gonzalez, R. Carrasco, A. Riesco and others. For references see Cold Spring Harbor Symposia on Quantitative Biology 10, 1942 and Medicina (Buenos Aires) 2, 1942.

Independently I made a similar statement in Chile in collaboration with my student Iglesias. We were able to establish two new facts of considerable interest. First, not only uterine but also extragenital subserous fibroids in the abdominal cavity can be elicited by estrogens—fibroids present themselves in the mesentery,

Fig. 2—Subserous parametric and apical tumors of the uterus. Tumors at the hilus and on the surface of the spleen and of the epiploon. Induced by a subcutaneously implanted pellet of estradiol. Absorption was of 15 mg daily in the course of eighty days.

the spleen, the pancreas, the abdominal wall and so on. And, second, under certain quantitative and timing conditions of treatment with estrogens a female guinea pig only rarely escapes production of abdominal fibroids.

The statement that abdominal fibroids can be elicited with such certainty gave us the opportunity to make a detailed study of the external and intrinsic factors responsible for this kind of experimental tumors. Extragenital abdominal fibroids were elicited without uterine fibroids being present, and they may be elicited also in the male though only rarely, there being a very pronounced sex difference as to the degree of the tumoral reaction. All estrogens, natural and artificial, free and esterified, were shown to be tumorigenic. The quantities necessary to elicit fibroids were with esterified estrogens very small, in experiments with subcutaneous injections the 17-capyrylic ester of estradiol prepared by Dr. C. Miescher in Basle proved to be the most powerful fibromatogenic substance. It may be assumed that the greater activity of this ester is due to its prolonged action or to greater facility offered by the ester to maintain a stable fibromatogenic threshold of blood estrogen. I stated that continuous action is an essential factor of tumorigenesis elicited by estrogens. When each week of injections was followed by two weeks free of treatment with a powerful tumorigenic ester we were able to prolong the experiment for an

entire year without fibroids being produced (Lipschutz, Rodriguez and Vargas). On the other hand, minute quantities of free estradiol quite insufficient to produce fibroids when given thrice weekly by subcutaneous injections proved to be highly active when absorbed by a steady flow from a pellet subcutaneously implanted by the method of Deanesly and Parkes.

The organism disposes seemingly by different means of autodefense of the toxic tumorigenic action of the estrogenic hormone. There is first the sexual rhythm or the alternation of high and low level phases of blood estrogen by which discontinuity of estrogenic action is assured. Transformation of ovarian estrogens to estradiol and estrone into urinary estrogens seems to serve the same purpose. We found estrone and equilin to be less fibromatogenic than estradiol and estrone even when a steady flow from a subcutaneous pellet is established. Fibromatogenesis was less frequent and of a minor degree when the estrogenic pellet was implanted not beneath the skin but into the liver. But as shall be shown later, it is very likely that the means of autodefense are not exhausted by inactivation or elimination of estrogens.

As early as 1924 I admitted that hormonal factors inhibiting the action of the estrogenic hormone on the effector tissue may be in play. Testicular tissue with fully developed seminiferous tubules and interstitial cells may lose its stimulative action on the development of the penis, prostate and seminal vesicles of the guinea pig when an ovary is engrafted which enters into

Fig. 3—Microscopic structure of experimental fibroids induced by estrogens. A: spindle shaped cells at the periphery and collagen fibers in the center. B: hypertrophied mesothelium and great wealth of collagen fibers between spindle shaped cells. C: infiltration and destruction of the pancreas by collagenous tissue of the fibroid. D: infiltration of the muscular wall of the rectum by a fibroid.

follicular development and prolonged endocrine activity. The reality of this kind of antagonism between steroid hormones has been fully corroborated in recent years by many workers. The estrous vaginal reaction elicited in

castrated mice or rats by estrogens is inhibited by the simultaneous administration of progesterone or testosterone propionate (W. M. Allen and Meyer, Courier), development of the comb in the cockerel elicited by local application of testosterone is inhibited by simultaneous application of estradiol (Morato), increase of the per-

estrogens is given, closed again in most of these experiments. But even when it remained open genital bleeding, a common phenomenon in guinea pigs subjected to prolonged treatment with estrogens, did not appear. Increase of uterine weight and endometrial proliferation were diminished. These results with pre-

vention of uterine and other fibroids acquired a more favorable quantitative aspect in experiments in which subcutaneously implanted pellets of steroid hormones were made use of. Weighed tablets of estradiol and of progesterone were implanted simultaneously in castrated guinea pigs, two months later the tablets were recovered and the quantity of the absorbed steroids was established by weighing again the dried tablet. We were rather surprised when the prevention of fibroids was effected with unexpectedly small quantities of progesterone. Instead of the ratio of one hundred and fifty as in our first experiments experimental fibroids were absent at a ratio of one to one with estradiol.

Fig 4—Continuous and intermittent (discontinuous) treatment with estrogens. At the bottom: Three injections weekly, total of forty seven injections of 20 mg of estradiol monobenzoate in the course of one hundred and thirteen days. Great increase in size of the uterus and large uterine fibroids (V 46). Uterus compressed by large parametric fibroid proliferation of the endometrium (V 44). At the top: Each week of injection was followed by two weeks and a half free of injections, total of forty seven injections of 80 mg of estradiol monobenzoate in the course of three hundred and sixty five days. Uterus of normal shape (though somewhat increased) and almost normal microscopic structure. Comparative figures at the same scale.

centage of chromophobe cells in the anterior lobe of the hypophysis elicited by the injection of estrogens is inhibited by the simultaneous administration of androgens (J. M. Wolfe and others). So one may assume that progesterone rhythmically produced in the body serves not only for synergetic action with the estrogen on the uterine mucosa but also for antagonistic action.

I thought that use may be made of these antagonistic or antiestrogenic actions of progesterone and testosterone in guinea pigs with experimental fibroids elicited by estrogens. Will abdominal fibroids be prevented by the simultaneous administration of the steroid hormones mentioned?

We started about three years ago with experiments in which simultaneously with oil solutions of fibromatogenic quantities of estradiol benzoate a multiple of progesterone or testosterone propionate was given. Progesterone was used in our first experiments at a ratio of one hundred and fifty as compared with estradiol because in former work of Courier the quantities of progesterone needed to prevent estrus in castrated rats injected with estrone were two hundred to four hundred times larger than the quantities of the latter. Uterine fibroids were prevented in all our experiments, the extragenital fibrous reaction was but slight, only small nodules being present on the surface of the spleen, stomach and surrounding parts of the abdominal wall, as may be observed in experiments with small quantities of the fibromatogenic estradiol. As to testosterone, we were equally successful by injecting quantities of testosterone fifty times greater than those of estradiol (Lipschutz, Vargas and others).

The antifibromatogenic action of the two steroids mentioned was concomitant with other preventive actions. The vagina instead of being permanently open, as is the case when a continuous treatment with

On account of the great similarity between the chemical structure of progesterone and desoxycorticosterone I had to ask myself whether the latter also may have a preventive action. This synthetic adrenal cortical steroid used as the acetate revealed itself in our work as a most powerful antifibromatogenic steroid. We have used this steroid also for studying more closely the quantitative aspects of antifibromatogenic action. In our subsequent work we found that a certain threshold quantity of the antifibromatogenic steroid must be absorbed daily from the subcutaneous pellet.

Fig 5—Comparative results with subcutaneously and intrahepatically implanted pellets of different estrogens. Height of columns indicates degree of the tumoral reaction. Absorption of estrogen was the same with the two subcutaneous and intrahepatic pellets. The tumoral reaction was considerably less with intrahepatic pellets.

so as to prevent the fibromatogenic action of the estrogen (Lipschutz, Luco and Zañartu). This antifibromatogenic threshold was smaller with progesterone than with other steroids. Desoxycorticosterone was nearest to progesterone as to its activity, whereas testosterone appeared to be less active.

The antifibromatogenic activity of desoxycorticosterone deserves special interest for the following reason. An antiestrogenic action of the adrenal cortex has been suggested already by former work of Zuckerman (1937), Del Castillo and Di Paola (1939) gave experimental evidence of such an action in the rat. Our findings with desoxycorticosterone show that this antiestrogenic action of the adrenal cortex may be attributed not only to cortical progesterone or cortical androgens but also to a specific cortical steroid. Indeed, desoxycorticosterone occupies a special place between cortical hormones in that it seems to be the only active cortical steroid without oxygen in the 11-position. Will other cortical hormones be able to prevent experimental fibroids as well as desoxycorticosterone? This is a question of greatest interest because it refers to the role which the adrenal cortex may play in the endocrine imbalance to which uterine fibromyoma probably is due. Thanks to the generosity of Dr. Kendall, we were able to make use of dehydrocorticosterone (substance A of Kendall), which was found to be antifibromatogenic. Are there other steroids in the body which might exert an antiestrogenic or antifibromatogenic activity?

Time will not permit me to discuss here this very relevant question. It is intimately related with two other ones: 1. How are differences of antifibromatogenic activity of the chemically related steroids dependent on differences of their chemical structure? and 2. Is antifibromatogenic activity of steroids coincident with their antiestrogenic progestational and masculinizing actions? On the basis of our comparative results with more than a dozen naturally occurring or naturally not occurring steroids I should wish to make only the following statements. Antifibromatogenic activity seems to be the expression of the antiestrogenic faculty of certain steroids and is not necessarily coincident with their progestational, cortical and estrogenic activity. This is a very important feature of the problem.

I have as yet spoken only of the prevention of fibroids. Will the same steroids also cause regression of existing

Can our findings be applied in the treatment of fibromyoma in the woman? The question may seem pretentious since testosterone propionate was already used in the treatment of uterine fibroids by different European and American gynecologists before there was any evidence of experimental fibroids or of fibromatogenic and

Fig. 7—Antifibromatogenic action of cortical steroids. 1 to 4 uteri of animals with subcutaneously implanted pellets of estradiol. 14 to 16 uteri of animals with pellets both of estradiol and of desoxycorticosterone acetate. 18 to 20 uteri of animals with pellets of both estradiol and dehydrocorticosterone (Kendall).

Fig. 6—Diagrams showing the antifibromatogenic action of progesterone in the guinea pig. At the left: Uterine and extragenital fibroids induced by a subcutaneous pellet of estradiol; absorption of estradiol was 66 mg daily in the course of two months. At the right: Prevention of uterine growth and of fibroids by the simultaneous implantation of a pellet of progesterone; absorption of estradiol was 70 mg daily and that of progesterone 40 mg daily in the course of two months.

uterine and other fibroids? This is very likely. Experimental fibroids begin to regress when injections of estrogens are suspended, and injection of an antifibromatogenic steroid is equivalent to suppression of estrogenic activity.

antifibromatogenic steroids. On the other hand, experimental fibroids elicited by estrogens are structurally different from the uterine fibroid or fibromyoma in women. Nevertheless the question of a practical application of our findings with antifibromatogenic steroids deserves interest, as shown by the following. Fibromyoma in women, like the experimental fibroid of the guinea pig, regresses when production of estrogen is suspended or diminished as is the case in the menopause or after castration or ovarian irradiation. Thus it has to be supposed that antifibromatogenic steroids which are antiestrogenic, i. e. are able to prevent the action of estrogens, will reveal their action also in the woman with fibromyoma. Injections of testosterone propionate have been administered for the treatment of fibromyoma with variable clinical success. In accord with our results one must assume that, with subcutaneous tablets or pellets of antifibromatogenic steroids, prospects may change greatly. The subcutaneous pellet assures a continuous flow of the antifibromatogenic steroid. The continuous flow of the estrogen is, as shown by our work, a fundamental condition of its

fibromatogenic action, and a thoroughful regulation of the flow of the antagonistic steroid likewise seems to be essential for its antifibromatogenic action

When discussing practical application of our experimental work with steroid hormones, one must not forget that the tumorigenic and antitumorigenic action of steroid hormones varies greatly according to the species. We failed to induce abdominal fibroids in the rat even with quantities of estradiol many times those necessary in the guinea pig (Lipschutz and Egaña and others), on the other hand, hypophyseal tumors as elicited by estrogens in the rat cannot be elicited in the guinea pig. These examples can be easily multiplied. On the other hand, testosterone propionate, which is considered antagonistic against atypical proliferation of the mammary gland in the woman, is in the guinea pig void of any inhibitory action on the mammary gland. I found metaplastic changes in the mammary gland more frequent with the simultaneous administration of estradiol and testosterone than with estradiol alone.

It is evident from the foregoing statements that a discussion on the most efficient fibromatogenic steroids for clinical trials cannot be given by the experimentalist. Progesterone is in the guinea pig the most potent antifibromatogenic steroid. Will it be so also in the woman? And will concomitant progestational action not be harmful? Will desoxycorticosterone be more desirable than progesterone? It is for the gynecologist to decide all these questions.

PANCREATIC DISEASE

THE FRANK BILLINGS LECTURE

JOSEPH H. PRATT, MD
BOSTON

The time will soon come when the one who gives the Billings lecture, as well as his audience, will belong to a generation that never knew Frank Billings. Those of us who did have the privilege of his friendship and who are indebted to him for help and leadership delight to honor his memory. Frank Billings can be characterized by a single word, "big." There was nothing small about him. He was a big man in body, in heart and in intellect. He had a big range of interests, civic as well as medical, and to him the American Medical Association owes much.

To another medical worthy, Reginald H. Fitz, contemporary and friend of Frank Billings, I owe an interest in pancreatic disease that began nearly forty years ago and has continued ever since. Dr. Fitz had been asked to contribute a paper on the symptomatology and diagnosis of pancreatic disease at the session of the Congress of American Physicians and Surgeons to be held in Washington in May 1903. Many months before the meeting he began to gather material for this paper, and he asked me to aid him. I have never seen any one make a more careful search of the literature or a more critical study of medical papers. He himself read and abstracted all the articles he had asked me to read and many others in addition. The paper that he wrote was the best and most informative on the subject of chronic pancreatic disease that had appeared and the equal in its way of his better known writings

on acute pancreatic disease published in 1889. The 1903 paper, buried in the Transactions of the Congress never directed or influenced the advance of knowledge as it would have done if it had received wider circulation.

Dr. Fitz¹ collected all the cases he could find in which chemical analyses of the fecal fats had been made, beginning with those of Friedrich Muller² who was the first to make chemical analyses in obstructive jaundice and in pancreatic disease. Fitz found support for Muller's view that in pancreatic disease there is less split fat in the feces, as in 9 out of the total of 11 cases in the literature the split fat was greatly diminished and consequently the neutral fat was increased.

In the opening paragraph of his paper Fitz quoted Friedrich's opinion³ that the presence of undigested, striated muscle fibers in the feces "is worthy of every consideration and may perhaps prove of diagnostic value." This statement was apparently based on a single but striking case reported by Fles⁴ in which the feces contained much fat and in addition large numbers of undigested striated muscle fibers. When the patient was fed daily a calf's raw pancreas, the fat and muscle fibers disappeared from the feces only to return again when the pancreas was omitted from the diet. The autopsy showed the pancreas reduced to a fibrous framework with only traces of gland substance. No duct could be found. Fitz found only 7 other cases of pancreatic disease with autopsy reports in which the presence or absence of muscle fibers and fat in the stools was noted. Steatorrhea was absent in 3, but cretorrhea was present in all 8. He concluded his paper by stating that "with the increase of chemical laboratories in our general hospitals, and with the more frequent addition of biological chemists to the force of pathologists, new lines of research are sure to be planned."

Dr. Fitz was eager to do his part in having these chemical studies continued, and he obtained a grant of money that enabled me to make a beginning. During the following year 1 case of obstruction of the pancreatic ducts, verified by autopsy, was studied in his service at the Massachusetts General Hospital with the aid of chemical procedures. The patient was a middle aged woman who had had a painless jaundice of six months' duration. She had lost nearly 50 pounds (23 Kg.). The stools were silvery gray and unformed and contained many muscle fibers with sharp edges and striations preserved and much fat in the form of flakes and crystals. Feces passed on Jan. 28, 1904 were dried and analyzed. They contained 54 per cent of fat, which was greater than that in any case in the literature collected by Fitz, his highest figure being 47 per cent, which was reported by Northrup and Herter⁵ in 1899 in the first study of this kind made in America. An analysis of a second stool passed on February 22, nearly a month later, yielded 63 per cent of fat, of which 29 per cent was neutral fat, 63 per cent fatty acids and only 8 per cent soaps. The second analysis showing an almost complete absence of soaps

5 Northrup W. P. and Herter C. A. Carcinoma of the Pancreas. Am. J. M. Sc. 117: 131, 1899.

supported the view advanced by Zoja⁶ that a low percentage of soaps is a valuable diagnostic sign of absence of pancreatic digestion. At autopsy there was a cancer of the pancreas, which appeared to have originated in the ampulla of Vater. The pancreatic ducts were occluded. I found later that a low percentage of soaps was not the rule in obstruction of the pancreatic ducts, as it did not occur in 3 of 6 cases.⁷

It is not the disturbance of fat digestion and absorption that is of greatest importance in the diagnosis of pancreatic insufficiency but the disturbance of protein digestion. After the study of a series of cases, I am convinced that the presence of many undigested muscle fibers in the feces when the patient is on a diet rich in meat is the simplest test of the existence of greatly diminished or absent pancreatic external secretion.

With the opening of the new buildings of the Harvard Medical School in 1906, adequate accommodations for the care of animals enabled me to carry on experimental studies on dogs over long periods of time. I decided to study the effect in dogs of excluding all the pancreatic juice from the intestine. It was a known fact that when the pancreas was extirpated there was a great disturbance in the digestion and absorption of protein and fat. A number of able experimenters had made studies of the absorption of nitrogen and fat after tying the pancreatic ducts in the dog and found it to be normal. When these animals were examined after death, it was claimed that no communication existed between the pancreatic ducts and the duodenum. Hence it was concluded that the external pancreatic secretion was not necessary for normal digestion and absorption to occur. One investigator, Otto Hess,⁸ however, had presented evidence that when all the pancreatic juice is excluded from the intestine severe disturbance of digestion and atrophy of the pancreas occur, but his work, published in an obscure journal, was disregarded.

The first 2 dogs that I studied threw light on the problem. The results on the first dog seemed to confirm the view generally held that the pancreatic juice was not necessary to good food absorption. The main pancreatic duct was cut between double ligatures, and all structures resembling small ducts were also tied. The dog was kept under observation over four months. There was an increase of weight of nearly a kilogram during the last month. The stools were normal in appearance and, on microscopic examination, no fat or muscle fibers were seen. In an absorption experiment after the ducts were tied 83 per cent of the fat fed was utilized, which is normal. The dog was killed. The pancreas was not atrophied and was of normal consistency. We were fortunate enough to discover on careful dissection a small sinus passing from the main duct above the ligated portion into the duodenum, which was conclusive evidence that pancreatic juice was still entering the intestine.

The success in the second experiment was due to the operative skill of Dr. F. T. Murphy. On Jan. 13, 1908 the pancreas was dissected away from the duodenum and the omentum was drawn down between the two structures and nearly encircled the duodenum. After recovery from the operation the dog began to pass bulky stools. These contained great numbers of muscle fibers with striations well preserved. In an absorption experiment lasting six days, from Janu-

ary 29 to February 3, the weight of the dried feces was 438 Gm., or 73 Gm. a day. This was in striking contrast to the results obtained in dog 1 with pancreatic juice entering the intestine through a postoperative sinus. The dried feces in an experiment of nine days' duration on this dog weighed only 57 Gm. or 6.3 Gm. daily, which was less than 10 per cent of the weight of the feces passed by the dog deprived of pancreatic digestion.

In this experiment on dog 2 with the pancreatic juice excluded from the intestine, only 11 per cent of the fat of the food was absorbed and only 22 per cent of the nitrogen. In February, 1908 the beneficial effect of a pancreatic ferment in increasing absorption of food was first demonstrated. In a six day feeding experiment 16 Gm. of pancreon was added to the food daily. The weight of the dried feces was reduced from 438 to 238 Gm. on the same diet. Forty-nine per cent of the fat and 62 per cent of the nitrogen were absorbed.

In order to appreciate the great reduction in the size of the pancreas produced by permanently occluding the pancreatic ducts some normal measurements will be given. The portion of a dog's pancreas that is attached to the duodenum is termed by Pfleger the corpus pancreatis. This was found by us in an unselected, medium sized dog to be 7 cm. long and 3 cm. wide. From the upper part of this extends the processus lienalis which in this dog control was 10.3 cm. long and 2.75 cm. wide. To the lower end of the corpus is attached the processus uncinatus, which is freely movable, being united only to the corpus. This measured 8.5 by 2.5 cm. The total length of this normal pancreas was 26 cm. Our first dog, which showed evidence of great disturbance in absorption of fat and protein, was killed on March 17, 1908, two months after the pancreas was separated from the duodenum. At autopsy a small shriveled, very firm, finely nodular to coarsely granular mass was seen occupying the position of the pancreas. It was grayish with fine reddish mottling. The processus lienalis was 2.5 cm. long, 0.5 to 1 cm. wide and 0.3 cm. thick. On cross section the main duct was present being from 1 to 1.5 mm. in diameter, colored fluid injected into this toward the duodenum did not enter the latter but led to a firm mass of tissue 3 by 2 by 1.5 cm. embedded in the adhesions about the duodenum, which was apparently the remains of the corpus pancreatis and processus uncinatus. Microscopically, small areas of pancreatic cells were found surrounded by dense connective tissue. Serial sections failed to show islands of Langerhans.

Experiments on 3 other dogs confirmed the results already obtained, as in every instance in which pancreatic secretion was excluded from the intestine there was diminution in the absorption of nitrogen and fat and great atrophy and sclerosis of the pancreas.

In the spring of 1909 Lamson, Marks and I⁹ presented our data at the meeting of the Association of American Physicians. The audience was not convinced. Dr. Meltzer¹⁰ said in the discussion of the paper that he regretted the fact that our findings varied from those of other observers. He concluded his remarks with the statement "The pancreas and the stomach both, as I pointed out some time ago, contain a good many factors of safety and by the removal of

one part, the other part is sufficient to take up the work of the other." Our results gained acceptance slowly. Heiberg¹¹ of Copenhagen in 1914, five years after our paper was published, and Adolf Schmidt¹² of Halle, Germany, a year later were the first to state that the evidence we presented was conclusive, and Brugsch¹³ was the first to confirm our work. Both of the last two authorities had previously expressed the view in their writings that the pancreatic juice was not essential to normal digestion.

Since the presentation of that paper, studies have been continued on more than 20 dogs in which the external secretion of the pancreas was excluded from the intestine. The results then stated have been amply confirmed. When the dogs were given a standard diet rich in carbohydrates and containing milk fat and vitamins, the absorption of nitrogen and fat was better than when they were given excessive amounts of food and fat in the form of lard. Absorption depended much on the general condition of the animal. Some of the dogs died of inanition, others were kept alive only by feeding raw pancreas. One dog, Zep, lived for more than thirty-four months after being deprived of pan-

tion. In nine experiments the last five of which were unreported until now (recorded in the accompanying table), the absorption of nitrogen ranged from 32 to 83 per cent and of fat from 9 to 88 per cent. The highest percentage of fat absorbed was on a milk diet. This confirmed Abelmänn's¹⁴ observation made many years ago that the emulsified fat of milk is better absorbed than any other form of fat by depancreatized dogs. As milk fat is well absorbed, it might be thought that the dog would gain weight on a milk diet but instead it resulted in the greatest loss. During a period of six days during which 3,780 cc of milk was given, the loss in weight was 200 Gm. It was thought that if the amount of milk was increased this loss would be reduced or a gain in weight would result. But when the amount of milk was nearly doubled the loss was even greater, amounting to 300 Gm.

The calories given daily ranged from 395 to 3,650. In nearly all the experiments the dog lost weight. It is evident from an inspection of the table that the dog's ability to digest and absorb nitrogen and fat varied from time to time. This point was confirmed and emphasized by Handelsman, Golden and Pratt.¹⁵

Record of Dog Zep

Experi- ment Number	Date	Weight In Grams	Total Food During Experiment	Calories		Absorption, In per cent
				Per Day	Per Kilogram per Day

creatic digestion by having the pancreas separated from the duodenum. The operation was performed by Dr. Murphy on Nov 19 1908. The dog's initial weight fell to 4,400 Gm by December 28, and then, unlike that of most of the other dogs without pancreatic secretion, it slowly rose, reaching 7 000 Gm in June 1909, but slowly dropped the following months, reaching 4,700 Gm on Feb 1, 1911 (chart 1). At this time the feeding of raw sheep's pancreas was begun. Three pancreases were given daily. The dog's weight increased to 6,900 Gm by March 15, a gain of over 2 000 Gm in five weeks. This was the first dog in which gain in weight and better absorption of protein and fat by the feeding of raw pancreas were demonstrated. The absorption of nitrogen rose to 83 and of fat to 85 per cent. During this four day experiment there was a positive balance of 7.2 Gm of nitrogen.

It was thought possible that in time gastric and intestinal enzymes might compensate for the loss of the pancreatic secretion, but this was not the case. The last experiment made on Zep, two and a half years after the first, showed no improvement in absorp-

tion in studies made later on a series of dogs. No diet was found which was regularly well absorbed.

When given a large amount of food, the dog had many stools daily and they were of large size. In one experiment of four days' duration (experiment 5) the dried stools weighed 2 700 Gm. In the moist state they would have weighed two to three times as much. Hence the dog weighing only 6,500 Gm passed feces in four days nearly equal to its weight. In none of the dogs in which the pancreatic juice was completely excluded from the intestine did fatty degeneration of the liver occur. As is well known, extensive fatty degeneration of the liver does frequently take place in depancreatized dogs. In our dogs rapid and pronounced atrophy of the pancreas occurred. It seems logical to conclude that the sclerotic pancreas in which both the acini and islands of Langerhans are largely destroyed is able in some way to prevent the development of a fatty liver. That these dogs did not develop diabetes is evidence that islet cells are still present and functioning. That fatty degeneration of the liver did

this disease before an operation is undertaken. The clinical signs are so obscure that formerly in very few cases was the diagnosis made except on the operating table. As the diastase value may fall to normal by the second or third day, the importance of making the test as soon as the patient is first seen is obvious. There is evidence that man, unlike the dog, may have higher

Chart 5—Urinary diastase in acute pancreatic edema with cholelithiasis

values in the urine than in the blood and that the elevated value persists longer in the urine. Hence the diastase content of the urine should always be determined. The safest course is to examine both blood and urine. I can recommend the improved Wohlgenuth test,²⁴ although it is chemically inaccurate because it is accurate enough for clinical diagnosis and requires simple equipment available in every hospital and a report can be made within an hour. More exact methods are those of Nørby²⁵ and Somogyi.²⁶ The latter is preferable. It is important to repeat the examination at least once every day if the first value obtained is moderately elevated. A rapid drop in diastase activity gives the first value obtained additional significance.

Acute pancreatic edema was not clearly recognized as a clinical condition until Zoepffel's paper appeared in 1922.²⁷ He described 4 cases of acute epigastric pain in which there was edema of the pancreas without necrosis. As it is not a true inflammation acute pancreatic edema is a better term than acute interstitial pancreatitis. This is the most common form of pancreatic disease. Unless diastase tests are made, it cannot be recognized. As it is usually associated with gallbladder disease in most of the cases it is mistaken for biliary colic or cholecystitis. It is usually mild, but in some cases it progresses and pancreatic necrosis results. I believe a routine examination of the urine for diastase should be made and made without the delay of even twelve hours in every case of severe acute pain in the upper part of the abdomen. The frequency of acute pancreatic edema is suggested by the fact that I have made daily examinations of the urine for diastase activity in 2 unselected cases of what appeared to be typical biliary colic. In both moderately increased diastase values were found in the urine, which dropped to normal within twenty-four hours but rose

again with the return of pain (charts 5 and 6). At operation some time later, gallstones were found in both cases.

Oser²⁸ recognized over forty years ago that bulky stools are suggestive of disease of the pancreas. He pointed out that they are notably excessive in quantity as compared with that of the food taken and are composed of undigested muscle fibers, fat and starch. The use of the Schmidt intestinal test diet is of aid in the diagnosis of obstruction of the pancreatic ducts, as it contains enough fat and rare meat to test the functional efficiency of the pancreas. Much information may be gained from the weight of the dried stools with the patient on the Schmidt diet.²⁹ The average weight of the dried feces in a series of 6 normal persons over a period of three days was 54 Gm. The maximum was 62 Gm.³⁰ I have given this diet to patients with various types of steatorrhea. In every instance when the dried stools weighed more than 300 Gm there was subsequently found obstruction of the pancreatic ducts. In 5 cases of cancer of the pancreas, the weight ranged from 340 to 463 Gm. The greatest weight occurred when the common bile duct as well as the pancreatic ducts were obstructed. In our experience the disease other than pancreatic disease in which the heaviest stools occur is tropical sprue. The maximum weight in obstruction of the common bile duct when the pancreatic ducts were not involved was 221 Gm.

Determination of the amount of nitrogen excreted in the feces is helpful in diagnosis as the value is low in sprue and obstructive jaundice and high in occlusion of the pancreatic ducts. In a case of obstruction of the common duct I obtained a daily excretion of only 11 Gm of nitrogen (Schmidt diet), in a case of sprue 27 Gm, and in a case of occlusion of the pancreatic ducts as much as 85 Gm. While the amount

Chart 6—Urinary diastase in acute pancreatic edema with cholelithiasis.

of nitrogen excreted in the feces is of diagnostic value, the percentage of nitrogen is of no value in differential diagnosis and the same is true of the percentage of fat. This is explained by the greatly increased weight of the stool in pancreatic disease.

The diagnosis of cancer of the pancreas has rarely been made except in the later stages of the disease. In a series of 53 autopsy records analyzed by Engleman,³¹ the condition was correctly diagnosed before the terminal two weeks in only 16 of the patients (30 per cent). The common idea that the disease is characterized by a painless jaundice is not true. Jaundice is often a late symptom, and 24, nearly 50 per cent, of Engleman's patients did not have jaundice throughout the course of the disease. Loss of weight is the most common symptom and frequently the first sign of disease. In two thirds of the Brigham Hospital cases it was the first symptom noticed by the patient (Kiefer³²). The average weight lost is more than 30 pounds (14 Kg). Pain is the next most frequent symptom. It may be either dull and continuous or severe and paroxysmal. The former is usually located in the midepigastrium, the latter in the region of the umbilicus. In 1 of our cases the abdominal pain was confined to the left lower quadrant. It may or may not be related to meals, it may be localized, or it may radiate to the right hypochondrium, the back, the chest, the shoulder or downward even to the legs. Speed³³ reported the pain as severe in 61 per cent of his 52 cases. As the disease in a large percentage of the cases is not recognized during life, Engleman's statistics based on autopsy records give a more accurate percentage of the frequency of the symptoms, especially jaundice, than those of Speed and Kiefer, which deal only with cases in which the diagnosis was made or confirmed at operation.

The association of loss of weight and abdominal pain with negative physical and gastrointestinal x-ray findings should always suggest the possibility of pancreatic cancer. In many of the cases the mistaken diagnosis of neurosis is made.

The importance of examining the stools grossly, microscopically and chemically has already been stressed. In most early cases, however, the stools are normal and constipation is frequent. In the past few years we have failed in our clinic to make the diagnosis in at least 6 cases of cancer of the pancreas. Jaundice was not present in any of these and the stools were normal. Glycosuria was not present. X-ray studies of the gastrointestinal tract were negative. Only 2 patients had abdominal pain, but all had a striking loss of weight, ranging from 15 to 50 pounds (7 to 23 Kg). In 3 the sedimentation rate was increased, in 1 it was 87 mm in one hour (Westergren).

Additional diagnostic aids are needed, and one that deserves to come into general use is the secretin test. Hammarsten³⁴ isolated secretin in a crystalline form and later produced a less costly preparation that can be employed as a clinical test. The Swedish investigators, Ågren and Lagerlöf³⁵ used a double barreled tube by means of which the gastric and duodenal secretions can be collected separately under continuous suction. When injected intravenously secretin produces within a minute or two an abundant flow of pancreatic juice, which usually amounts to 150 cc or more in one hour. The greatest volume I have obtained was 264 cc.

In 1 case 100 cc was collected in ten minutes. I have injected secretin into nearly 100 patients without untoward results. A second injection in the same subject has produced no unpleasant symptoms. The volume secreted in one hour, the hydrogen ion concentration, the alkalinity expressed in milliequivalents of bicarbonate, the concentration and units of enzymes (diastase, trypsin, lipase and phosphatase) and bilirubin have all been determined in my cases. As in the study of gastric secretion the determination of the acidity is of far more value than the activity of the pepsin so Werthessen³⁶ has presented evidence by the statistical study of reported cases that the alkalinity of the pancreatic juice and not the enzyme values as determined by present day methods are of diagnostic value.

In all 5 proved cases of cancer of the pancreas studied in our clinic by means of the secretin test the volume, the alkalinity of the pancreatic juice and the concentration of the enzymes were greatly reduced.³⁷ In only 1 were creatorrhea and steatorrhea present. Hence without the secretin test no evidence of pancreatic insufficiency would have been discovered. In some cases of cancer of the pancreas studied by others the secretin test has yielded normal values (Lagerlöf,³⁸ Comfort³⁹ and Pollard and his co-workers⁴⁰).

Furthermore, if a low alkalinity and low enzyme concentrations are obtained one cannot conclude that the patient necessarily has organic disease of the pancreas, as I⁴¹ have observed 2 cases of transitory hypochylia pancreatica in which the volume, alkalinity and enzymes were reduced as greatly as in cases of cancer. No similar cases have been found by others who have employed the secretin test. Hence the probability of organic disease exists if low values are found.

It is well to determine the serum lipase in all cases of suspected cancer of the pancreas as Comfort and Osterberg⁴² found it increased in 28 out of 69 cases, or 40.5 per cent, and in 6, or 67 per cent of 9 cases in which there was cancer of the ampulla of Vater. Occasionally the diastase in the blood or urine has been found increased in cancer of the pancreas. This occurred in 2, or 8 per cent, of Comfort's 24 cases and in 1 of my cases.

The importance of the early diagnosis of cancer of the pancreas has been greatly increased since American surgeons, led by Allen O. Whipple, have demonstrated the possibility of successful extirpation of the duodenum and head of the pancreas in this disease. In his Bigelow Lecture delivered last fall Whipple⁴³ reported the case of a 47 year old woman who had no postoperative complications after a one stage radical duodenopancreatectomy. She regained 20 pounds (9 Kg) and was free from symptoms nineteen months after operation. He has had 5 patients who survived for periods of five to twenty-eight months after the

radical operation Whipple excludes the pancreas from all connection with the intestinal tract This would result in a serious disturbance of absorption of fat and nitrogen, as has been emphasized repeatedly in this lecture, if sinuses did not speedily form and carry the pancreatic juice into the intestine It will probably be found wise to implant the stump of the pancreas into the wall of the stomach or jejunum, as it is certain that the essential pancreatic juice will not find its way from pancreas to intestine in all cases

The reasons for making an early diagnosis of pancreatic disease can be briefly stated Early diagnosis of acute pancreatic edema and pancreatic necrosis is essential to avoid needless operation Early diagnosis of cancer of the pancreas permits of radical operation which holds promise of prolongation of life and increased comfort and the possibility of cure In diagnosing acute disease the determination of diastase in the blood or urine is essential In diagnosing cancer of the pancreas the secretion test is a great aid, but to recognize the disease in its early stage the diagnostic significance of loss of weight with pain in any part of the abdomen in the absence of disease of stomach and intestine should be recognized The diagnosis is most often missed because physicians forget that the patient has a pancreas

30 Bennet Street

THE SO-CALLED MUCOUS COLITIS OR SPASTIC IRRITABLE COLON

CHARLES W. MCGAVRAN, M.D.
COLUMBUS, OHIO

This is not a disease it is a condition It is due to a disturbance in the vegetative or autonomic nervous system Usually it is neurogenic in origin, although often it is the result of irritation either in the gastrointestinal tract or in the organs adjacent to the gastrointestinal tract While not critically ill, these patients, because of their anxiety, are really sick The mortality is nil but the morbidity is great Because the pain of a spastic irritable colon can simulate the pain associated with disease of any organ of the abdomen, the patient should not be subjected to surgical or even stringent medical therapy without the benefit of adequate study

The story the clinician so frequently hears when he is consulted by a patient suffering from "the so-called mucous colitis or spastic irritable colon" is illustrated by the following case history

A married woman of 46 complains of colicky pains in the abdomen, excessive gas with belching, palpitation, constipation sleeplessness, nervousness and fatigue This started nine years ago, soon after the death of her mother from cancer, as a recurrent pain in the right lower quadrant always associated with distention and belching She was told that she had appendicitis, and the appendix was removed This was only the first of a series of operations There followed, in fairly rapid succession, a cholecystectomy, an exploratory operation at which some adhesions were severed, and finally a nephropexy None of these gave her relief Instead the attacks became more frequent and severe She became nervous and developed palpitation She no longer can sleep properly and is always tired She has obstinate constipation, but the laxatives prescribed only aggravate the pain Advice by several physicians that there was nothing seriously wrong and to go home and forget it

only has made her more apprehensive She is sure she is really sick She is miserable She has lost weight She fears cancer She is most anxious to find out just what is wrong She is willing to do anything, even to be operated on again to get relief

Yes, this is the story the clinician so frequently hears and, in an effort to prevent such a story from developing, this paper is being presented today I wish to emphasize the fact that the patient cannot be benefited by repeated surgical attempts to remove all sources of pain, as is illustrated in the case cited, nor can he be benefited by being told that he has no organic disease, to go home and forget it The only way the physician can render a service to such a patient is by being painstaking, deliberate and thorough in, first, taking the history and listening with interest to every detail of the complaints, second, making his physical, clinical and roentgenologic examinations, and, third, interpreting his findings and outlining the plan of management

As the origin of many cases of spastic irritable colon is neurogenic, the therapy begins as we take the history From the start we must study the individual and then the condition from which the individual is suffering This means a personal interest on the part of the clinician throughout the entire diagnostic procedure in order that he may gain the patient's confidence Even though the history points directly toward a functional disease the clinician should proceed with a thorough physical and clinical examination—for sometimes in the most pronounced neurotic there will be found some organic lesion acting as an irritant The physical examination must be complete, looking for foci of infection, error in refraction, disease in the cardiorespiratory systems, as well as making the usual abdominal examination A proctoscopic and sigmoidoscopic examination should be made on every patient A pelvic examination in the female and a digital examination of the prostate in the male are necessary

In the typical case the physical examination reveals an undernourished, asthenic individual The colon especially the sigmoid colon, is palpable cordlike and tender The cecum often is distended and tender There may be generalized tenderness and distention As a routine the urine, blood, feces and gastric contents should be studied The characteristic stool consists of scybalous masses or ribbon-like stools covered with mucus At times mucous casts of the colon are brought in and often these harmless casts cause the patient much alarm There are no characteristic findings in the urine blood or gastric analyses in this condition, but these examinations must be made in order to rule out contributory diseases

A complete gastrointestinal fluoroscopic and roentgenologic examination, including a barium enema, should be made Next to the history this examination more than any other throws light on the case It shows the condition of the cardia, the presence of a hiatus hernia or a peptic ulcer It sometimes picks up an early gastric carcinoma in the operable zone It shows the motility throughout the entire gastrointestinal tract It might reveal the presence of a carcinoma of the colon, a regional ileitis, a megacolon or intestinal diverticula When no pathologic condition is demonstrated we have the picture of the spastic colon to show the patient as we explain our findings

The examination of the gallbladder should include x-ray study and a gallbladder drainage This study reveals the presence or absence of stones and infection and shows the functional capacity of the gallbladder

One should make a plain roentgenogram of the kidneys, ureters and bladder, paying particular attention to the size and location of the kidneys and looking especially for any opaque shadow that might indicate a calculus in the urinary tract. In some instances it is necessary to make a complete urologic study.

TREATMENT AND MANAGEMENT

If the study has shown organic disease treatment is planned as indicated. Success in treating the neurogenic phase depends on gaining the confidence and cooperation of the patient. The history, the complete summary of the physical findings and their interpretation, and the diagnosis must be discussed with the patient. I make it a policy to dictate all my observations in the presence of the patients. I then attempt to explain the function of the vegetative nervous mechanism and especially what it has to do with digestion. I tell them the mechanism of a spastic irritable colon. I encourage questions. I never under any circumstances belittle their suffering but stress the point that there is nothing seriously wrong. I try to take away from them their every worry, for worry and anxiety increase the suffering. I tell them that they must expect the colon to become spastic and irritable after any severe physical or nervous strain. They are told to consider these return attacks as detours, not to regard them seriously but to go on about their work and soon the attack will abate and they will be back on the good road again. As has been said, they must learn to get well with the spastic irritable colon and not try to get well of it.

It has been my experience that this frank and candid understanding between the patient and the physician is of utmost importance. I have several copies of "Nervous Indigestion"¹ and these books are always out being read by nervous, irritable colon patients and it helps them in the "getting better" effort. It seems that reading something that has been written for the physician makes an impression on them—in other words, it helps them to believe.

SEDATIVES AND ANTISPASMODICS

Sedatives and antispasmodics are given in quantities sufficient to quiet the general nervousness and relax the painful spasm in the colon until such time as the patient is able to control his symptoms. After a complete understanding, some of the more stable patients will get along without any at all. Some will need only a mild sedative at bedtime. It is important that these people sleep, for a good rest for several nights in succession will go a long way toward restoring a disturbed nervous system. In extreme nervousness, large doses of sedatives must be given, enough to quiet the patient until he is able to get hold of himself. I usually give antispasmodics in combination with a mild sedative three or four times a day. This is most effective about twenty minutes before meals, because the spasm is often aggravated by the ingestion of food. As sedatives I give one of the barbiturate preparations and when large doses are necessary, I combine sodium bromide with elixir of phenobarbital. As antispasmodics, atropine sulfate, tincture of belladonna or one of the newer synthetics is quite effective. When giving large doses of sedatives and antispasmodics it is necessary to be careful to watch for toxic reactions. For this reason I always discontinue the use of belladonna two days out of seven. The

dosage should be gradually lessened until finally the patient can get along without any regular sedative or antispasmodic. He should always keep some handy, however to use for the relief of recurrent attacks which are bound to come from time to time. If he knows that he has medicine which will relieve the pain when it starts, he will have less fear.

DIET

Diet is important in treating patients with a spastic colon, not so much in restricting them as in getting them to eat enough. They seldom are ill because of what they have eaten but many put the blame for their every gastrointestinal symptom on some particular food they have had. They are afraid to eat and as a result are undernourished. I encourage them to take an adequate balanced diet. With the more severe case it is necessary to start with a smooth bland diet eliminating coarse foods with seeds or skins raw fruits and vegetables and fried foods. One can soon relax these restrictions allowing the patient to take anything he can tolerate. The old adage "the proof of the pudding is the eating" should be followed literally.

I find it expedient to add vitamins. There is usually a multiple deficiency and a multiple vitamin capsule is indicated. Additional B complex in a concentrated form or as brewers' yeast and additional vitamin C are often necessary. For some of the extremely nervous persons I have found that niacin (nicotinic acid) 50 mg three times a day is of benefit.

ALLERGY

Space does not permit a detailed analysis of food allergy and its possible relation to spastic irritable colon, but it should ever be borne in mind that some patients are sensitive to various foods and that when this sensitivity exists only the elimination of that particular food from the diet will give relief. To determine the exact food to which the patient is sensitive often requires the services of an experienced allergist.

LAXATIVES

Most of these patients suffer from constipation and have for years. They have tried various laxatives most of which have acted as an irritant. I mention castor oil and phenolphthalein only to condemn them for patients suffering from an irritable colon. Liquid petrolatum, plain or combined with agar often gives very satisfactory results. With some it may be necessary to add magnesium magma or nonirritating bromine gum bulk producer. Plain petrolatum in doses of from 1 to 4 teaspoons a day will often act well as a nonirritating laxative. Some patients will get along very well on a small saline or plain water enema. The physician must ascertain what procedure is best suited for a particular patient. Castor oil is effective in treating an acute relapse, which will occur despite the best efforts of both patient and physician. When the patient reports a severe colicky pain abdominal distention, nausea and the passing of nothing but mucus, about 3 ounces of castor oil followed in thirty minutes by a teaspoon of paregoric will usually give relief.

Thus I have outlined a plan for the diagnosis and management of spastic irritable colon. It includes individualization of the highest order, thoroughness in the diagnostic procedure, frankness in the interpretation of the findings, kindness, sympathy, and yet firmness in outlining the course of treatment.

¹ Alvarez W. C. Nervous Indigestion ed 2 New York Paul B Hoeber 1931

radical operation Whipple excludes the pancreas from all connection with the intestinal tract This would result in a serious disturbance of absorption of fat and nitrogen, as has been emphasized repeatedly in this lecture, if sinuses did not speedily form and carry the pancreatic juice into the intestine It will probably be found wise to implant the stump of the pancreas into the wall of the stomach or jejunum, as it is certain that the essential pancreatic juice will not find its way from pancreas to intestine in all cases

The reasons for making an early diagnosis of pancreatic disease can be briefly stated Early diagnosis of acute pancreatic edema and pancreatic necrosis is essential to avoid needless operation Early diagnosis of cancer of the pancreas permits of radical operation which holds promise of prolongation of life and increased comfort and the possibility of cure In diagnosing acute disease the determination of diastase in the blood or urine is essential In diagnosing cancer of the pancreas the secretion test is a great aid but to recognize the disease in its early stage the diagnostic significance of loss of weight with pain in any part of the abdomen in the absence of disease of stomach and intestine should be recognized The diagnosis is most often missed because physicians forget that the patient has a pancreas

THE SO-CALLED MUCOUS COLITIS OR SPASTIC IRRITABLE COLON

CHARLES W. MCGAVRAN, M.D.
COLUMBUS, OHIO

This is not a disease, it is a condition It is due to a disturbance in the vegetative or autonomic nervous system Usually it is neurogenic in origin, although often it is the result of irritation either in the gastrointestinal tract or in the organs adjacent to the gastrointestinal tract While not critically ill, these patients, because of their anxiety, are really sick The mortality is nil but the morbidity is great Because the pain of a spastic irritable colon can simulate the pain associated with disease of any organ of the abdomen the patient should not be subjected to surgical or even stringent medical therapy without the benefit of adequate study

The story the clinician so frequently hears when he is consulted by a patient suffering from "the so-called mucous colitis or spastic irritable colon" is illustrated by the following case history

A married woman of 46 complains of colicky pains in the abdomen, excessive gas with belching, palpitation, constipation, sleeplessness, nervousness and fatigue This started nine years ago, soon after the death of her mother from cancer, as a recurrent pain in the right lower quadrant always associated with distention and belching She was told that she had appendicitis, and the appendix was removed This was only the first of a series of operations There followed in fairly rapid succession, a cholecystectomy, an exploratory operation at which some adhesions were severed, and finally a nephropexy None of these gave her relief Instead the attacks became more frequent and severe She became nervous and developed palpitation She no longer can sleep properly and is always tired She has obstinate constipation, but the laxatives prescribed only aggravate the pain Advice by several physicians that there was nothing seriously wrong and to go home and forget it

only has made her more apprehensive She is sure she is really sick She is miserable She has lost weight She fears cancer She is most anxious to find out just what is wrong She is willing to do anything, even to be operated on again to get relief

Yes, this is the story the clinician so frequently hears and, in an effort to prevent such a story from developing, this paper is being presented today I wish to emphasize the fact that the patient cannot be benefited by repeated surgical attempts to remove all sources of pain, as is illustrated in the case cited, nor can he be benefited by being told that he has no organic disease, to go home and forget it The only way the physician can render a service to such a patient is by being painstaking, deliberate and thorough in, first, taking the history and listening with interest to every detail of the complaints, second, making his physical, clinical and roentgenologic examinations, and, third, interpreting his findings and outlining the plan of management

As the origin of many cases of spastic irritable colon is neurogenic, the therapy begins as we take the history From the start we must study the individual and then the condition from which the individual is suffering This means a personal interest on the part of the clinician throughout the entire diagnostic procedure in order that he may gain the patient's confidence Even though the history points directly toward a functional disease, the clinician should proceed with a thorough physical and clinical examination—for sometimes in the most pronounced neurotic there will be found some organic lesion acting as an irritant The physical examination must be complete, looking for foci of infection, error in refraction, disease in the cardiorespiratory systems, as well as making the usual abdominal examination A proctoscopic and sigmoidoscopic examination should be made on every patient A pelvic examination in the female and a digital examination of the prostate in the male are necessary

In the typical case the physical examination reveals an undernourished, asthenic individual The colon, especially the sigmoid colon is palpable cordlike and tender The cecum often is distended and tender There may be generalized tenderness and distention As a routine the urine, blood, feces and gastric contents should be studied The characteristic stool consists of scybalous masses or ribbon-like stools covered with mucus At times mucous casts of the colon are brought in and often these harmless casts cause the patient much alarm There are no characteristic findings in the urine, blood or gastric analyses in this condition, but these examinations must be made in order to rule out contributory diseases

A complete gastrointestinal fluoroscopic and roentgenologic examination, including a barium enema should be made Next to the history this examination more than any other throws light on the case It shows the condition of the cardia, the presence of a hiatal hernia or a peptic ulcer It sometimes picks up an early gastric carcinoma in the operable zone It shows the motility throughout the entire gastrointestinal tract It might reveal the presence of a carcinoma of the colon, a regional ileitis or megacolon or intestinal diverticula When no pathologic condition is demonstrated we have the picture of the spastic colon to show the patient as we explain our findings

The examination of the gallbladder should include x-ray study and a gallbladder drainage This study reveals the presence or absence of stones and infection and shows the functional capacity of the gallbladder

One should make a plain roentgenogram of the kidneys, ureters and bladder, paying particular attention to the size and location of the kidneys and looking especially for any opaque shadow that might indicate a calculus in the urinary tract. In some instances it is necessary to make a complete urologic study.

TREATMENT AND MANAGEMENT

If the study has shown organic disease, treatment is planned as indicated. Success in treating the neurogenic phase depends on gaining the confidence and cooperation of the patient. The history, the complete summary of the physical findings and their interpretation, and the diagnosis must be discussed with the patient. I make it a policy to dictate all my observations in the presence of the patients. I then attempt to explain the function of the vegetative nervous mechanism and especially what it has to do with digestion. I tell them the mechanism of a spastic irritable colon. I encourage questions. I never under any circumstances belittle their suffering but stress the point that there is nothing seriously wrong. I try to take away from them their every worry, for worry and anxiety increase the suffering. I tell them that they must expect the colon to become spastic and irritable after any severe physical or nervous strain. They are told to consider these return attacks as detours, not to regard them seriously but to go on about their work and soon the attack will abate and they will be back on the good road again. As has been said, they must learn to get well with the spastic irritable colon and not try to get well of it.

It has been my experience that this frank and candid understanding between the patient and the physician is of utmost importance. I have several copies of "Nervous Indigestion"¹ and these books are always out being read by nervous, irritable colon patients and it helps them in the "getting better" effort. It seems that reading something that has been written for the physician makes an impression on them—in other words, it helps them to believe.

SEDATIVES AND ANTISPASMODICS

Sedatives and antispasmodics are given in quantities sufficient to quiet the general nervousness and relax the painful spasm in the colon until such time as the patient is able to control his symptoms. After a complete understanding, some of the more stable patients will get along without any at all. Some will need only a mild sedative at bedtime. It is important that these people sleep, for a good rest for several nights in succession will go a long way toward restoring a disturbed nervous system. In extreme nervousness, large doses of sedatives must be given, enough to quiet the patient until he is able to get hold of himself. I usually give antispasmodics in combination with a mild sedative three or four times a day. This is most effective about twenty minutes before meals, because the spasm is often aggravated by the ingestion of food. As sedatives I give one of the barbiturate preparations and, when large doses are necessary, I combine sodium bromide with either of phenobarbital. As antispasmodics, atropine sulfate, tincture of belladonna or one of the newer synthetics is quite effective. When giving large doses of sedatives and antispasmodics it is necessary to be careful to watch for toxic reactions. For this reason I always discontinue the use of belladonna two days out of seven. The

dosage should be gradually lessened until finally the patient can get along without any regular sedative or antispasmodic. He should always keep some handy, however, to use for the relief of recurrent attacks which are bound to come from time to time. If he knows that he has medicine which will relieve the pain when it starts, he will have less fear.

DIET

Diet is important in treating patients with a spastic colon, not so much in restricting them as in getting them to eat enough. They seldom are ill because of what they have eaten but many put the blame for their every gastrointestinal symptom on some particular food they have had. They are afraid to eat and as a result are undernourished. I encourage them to take an adequate balanced diet. With the more severe case it is necessary to start with a smooth, bland diet eliminating coarse foods with seeds or skins raw fruits and vegetables and fried foods. One can soon relax these restrictions, allowing the patient to take anything he can tolerate. The old adage "the proof of the pudding is the eating" should be followed literally.

ABSTRACT OF DISCUSSION

DR WALTER C ALVAREZ, Rochester, Minn. This is an excellent description of a very common disease. I feel strongly that we should never call the syndrome by the term colitis. I object to that term because I have to spend many hours each week trying to reassure women who have been much frightened by this diagnosis. What happens sometimes is that they think they have chronic ulcerative colitis. I feel strongly that we physicians should tell these people that they have a normal colon. It is a normal colon. It looks that way at operation or at necropsy and it really looks normal enough in roentgenograms. Where I work the roentgenologists report all these so called spastic colons as normal. Of course they are spastic because the woman is tense and nervous. The colon is not ulcerated or inflamed. The trouble is that nerves are playing tricks with it. I don't care where the colon lies in the abdomen. It is a tube in which material is pushed along not by gravity but by muscular action. Hence what difference can it make whether it is near the navel or down in the pelvis? Kinks also are normal and cause no trouble. Some colons are big and roomy and some are smaller. Some have a long sigmoid loop and some do not. All these variations can be found in healthy athletes, so we must not talk to people about them. We must not make anxiety neuroses in our patients. We can't promise these people a cure. Once one has a sensitive colon one is likely to have it all one's life. I inherited one from my mother, and I know I shall never lose it. If I get too tired or emotionally upset or am coming down with a cold or if I eat something to which I am allergically sensitive I get a sore colon. I have learned to live amicably with that colon and I try to teach my patients to do the same. I ask them so to live that their colon won't ruin their life. Whatever we physicians do we must never operate on these people because of their sore colon. I don't think we should keep them filled up with phenobarbital all day and every day. I permit a sedative only on a day when the colon is in an uproar.

DR W COLE DAVIS, Atlantic City, N. J. I feel that no colitis is a true colitis unless there is blood. If there is no blood in the mucus it is of neurogenic origin. Patients who are sent to me sometimes after being in the hands of a general practitioner, are sent to me not because the general practitioner was incapable of handling them or because he didn't have an insight into the condition but chiefly because he hasn't time to bother with the patient or is not interested in persons who take a great deal of time. Unless one has time to spend, at least an hour, with a patient whose illness is of neurogenic origin taking the history and listening to him talk, one should not even bother with him. If one takes a patient and merely gives him sedatives because he cannot sleep one is not going to do him any good at all unless one can go into his problem. All of the multitudinous varieties of barbiturates that are being put out now are used to great excess and are very much to the detriment of the patients. They are dangerous drugs, very easily habit forming with nervous patients.

DR MYER SOLIS-COHEN, Philadelphia. Neurogenic disturbances, including those of the gastrointestinal tract, such as irritable colon, gas and nervous indigestion are frequently produced by bacterial toxemia due to focal infection. We should always examine the tonsils pressing on them to see if pus can be expressed. An expert should examine the sinuses. The whole mouth should be roentgenographed—not only the teeth but also the spaces where teeth have been removed. A tonsillectomy doesn't mean removal of infection, because after tonsillectomy the infecting organisms often remain in the tonsillar spaces in the nasopharynx and in other parts of the throat. Nor does the fact that the sinuses have been opened and drained mean that the focus of infection has been removed because the organism may still remain in the nose and still infect the patient. While it is necessary to remove infected tonsils, teeth and roots and to drain infected sinuses, this does not necessarily remove the bacterial focus of infection which is causing the toxemia and the secondary symptoms. We must in addition increase the patient's resistance to the infecting organism so that any organisms left in the nose and in the throat will be killed and

their toxins will be combated. That is done by means of a vaccine containing the infecting organism. An ordinary culture, however, tells only what organisms are present and may not even contain the organism causing the infection. It does not tell which of the several organisms present is causing the infection. In the pathogen selective culture, two simultaneous cultures are made, one in a rich medium, such as brain broth, and the other in the patient's fresh, whole, coagulable blood, the idea being that the organisms that are killed by the patient's blood are not infecting him, while the organisms that grow in his blood are those against which he has no bactericidal power and which are probably infecting him or are capable of infecting him. Ninety per cent of the pathogen selective vaccine consists of the organisms that grew in the blood and 10 per cent consists of the other organisms. It has to be administered very cautiously because the dose may vary a million or a trillion times. When it is administered properly, the patient frequently develops resistance to his infection, kills off the infecting organisms, combats the toxemia and loses his nervousness, nervous indigestion, irritable colon and other symptoms.

DR C W MCGAVRAN, Columbus, Ohio. I have nothing to add to the discussion. I want to thank the gentlemen who have discussed this paper. I agree with them thoroughly. I want Dr. Cohen to understand that the very first thing I said to do in the line of making a complete survey was to search for foci of infection.

SULFATHIAZOLE IN EPIDEMIC
SONNE DYSENTERY

HERMAN YANNET, M.D.

ALBERT LEIBOVITZ, M.S.

AND

JOYCE V. DEUTSCH, M.D.

SOUTHBURY, CONN.

The beneficial effects of sulfathiazole and sulfaguanidine on the clinical course of endemic bacillary dysentery has been clearly demonstrated.¹ The febrile period and the length of time during which abnormal stools occur are definitely shortened. Insufficient data, however, are available to evaluate the effects of the sulfonamide drugs on the two factors which have important epidemiologic implications, namely the length of time elapsing before the dysentery bacillus can no longer be demonstrated in the stools and the incidence of relapses. The importance of these two factors in the control of epidemics occurring in institutions, schools, camps and the like has been frequently stressed. Our purpose in the present communication is to describe the study of a relatively small outbreak of Sonne dysentery in which data were obtained bearing on these two points.

METHODS

Material for cultural study was obtained by the insertion of a finger, protected by a finger cot moistened with tap water, into the rectum and rubbing the finger over the mucosa, fecal masses being avoided if possible. After this procedure the finger cot was cleaned by a cotton applicator that had previously been tubed and sterilized in 3 cc. of a 30 per cent glycerin-saline solution. The contaminated applicator was then replaced in the glycerin-saline tube. The glycerin-saline solu-

tion² was composed of glycerin 300 cc, water (distilled) 700 cc, sodium chloride 6 Gm, dipotassium hydrogen phosphate 31 Gm and potassium dihydrogen phosphate 1 Gm

By this means specimens could be obtained from many persons in a short space of time and subsequent plating could be expedited. The use of rectal swabs has been shown to yield a much higher incidence of positive stool cultures than the use of the whole stool³. The effectiveness of the glycerin-saline solution for preservation and transportation has been previously described by Wu and Sia⁴ and by Sachs⁵.

At the laboratory, the exposed swab was thoroughly agitated in the glycerin-saline solution, removed and used to place a large drop of the suspension on a MacConkey's plate (Difco). After subsequent streaking of the entire surface of the medium with a wire spreader, the plate was incubated at 37 C for twenty-four hours. Suspicious colonies were fished out, inoculated into Kligler's iron agar (Difco) tubes and again incubated. Tubes showing acid butts, alkaline slants and no gas or hydrogen sulfide formation were then subjected to further study by appropriate biochemical and serologic procedures to determine whether *Shigella* organisms were present.

The effectiveness of this procedure is indicated by the fact that initial cultures were positive for *Bacterium sonnei* in 43 out of 44 patients with clinical dysentery. The organism was isolated from the forty-fourth patient during subsequent cultures.

BACTERIOLOGY

The Sonne organisms isolated during the outbreak had the following characteristics. On MacConkey's medium the colonies were white, 3 to 5 mm in diameter, opaque, smooth to lobate edged and slightly convex. A central red color was present in a few instances in twenty-four hours and in almost all cases after several days' growth. The biochemical characteristics are given in table 1. Immune rabbit serum prepared against one of the first strains isolated agglutinated all the strains isolated to an average titer of 1:2,560⁶.

During our investigation of the 166 inhabitants of the three infected cottages, carriers of *Shigella* organisms other than *Bacterium sonnei* were discovered. Seven were carriers of *Shigella alkalescens*, 9 of *Shigella ceylonensis* and 8 of a probable anaerogenic coliform organism which resembled *Shigella ceylonensis* biochemically but differed by being motile. The production of indole and the fermentation of dulcitol served to differentiate these organisms from *Bacterium sonnei*. Their biochemical behavior is also summarized in table 1. The significance of these organisms as probable pathogens is still undetermined, they did not appear to play a significant role in the present epidemic.

Rectal cultures, obtained in the manner previously described, of 300 new admissions revealed 3 carriers of *Bacterium sonnei*, 4 of *Shigella alkalescens* and 2 of unidentified, presumably nonpathogenic species. The

Sonne strains isolated from the new admissions were shown to differ biochemically from the epidemic strain in being rapid rhamnose fermenters. Dr. Kenneth M. Wheeler⁷ of the Connecticut State Department of Health Laboratories has noted that almost all strains of *Bacterium sonnei* isolated in Connecticut fermented rhamnose within twenty-four hours whereas our epidemic strain required from two to eleven days to ferment this carbohydrate.

DESCRIPTION OF THE EPIDEMIC

At the time the first case appeared there were approximately 600 inmates living in eighteen cottages each housing about 40. Each cottage is a complete unit with its own kitchen, dining room, sleeping quarters, cooks and attendants. The only significant contact between the cottages was through certain cooks and attendants who served in several cottages as relief per-

* Number of strains studied.

† Average number of days required by positive strains to ferment the carbohydrates. All the strains studied were grain negative rods that fermented the carbohydrates with acid but no gas formation. Fermentation reactions were carried out for twenty-one to twenty-eight days.

‡ Excludes the three new admission strains that ferment this sugar in twenty-four hours.

sonnel. However, laundry and stores are centralized. Cases of dysentery appeared in only three of the eighteen cottages. The original source of the outbreak and the method of spread to the other two cottages, which were in widely separated parts of the institution, could not be ascertained in spite of careful search. It is not unlikely, however, that a temporary carrier state among some of the relief personnel was responsible although the organisms could not be isolated at any time from these persons.

The same general procedure for controlling the epidemic was followed in all of the cottages involved. All persons with clinical symptoms of the disease were transferred to the institution's hospital. Cultures were taken on all inmates remaining in the cottage and the inmates were then separated within the cottage into two groups, depending on the results of the culture, i.e., whether or not *Bacterium sonnei* was present. On recovery from the acute illness, the patients were

returned to their respective cottages and placed in the Sonne positive group. Stool cultures were carried out on the positive group at about weekly intervals. When two consecutive cultures were negative, the person was placed in the negative group. Cultures were carried out on the negative group at less frequent intervals.

The clinical course of the disease was relatively mild. The onset was sudden with abdominal cramps, diarrhea and, in most instances, vomiting. Fever, ranging from 100 F to 105 F, was present in more than 75 per cent of the cases. Gross blood was observed in only 3 cases; parenteral fluid was administered in 2 cases. None of

the patients appeared seriously ill and there were no fatalities. Of the 44 patients with clinical dysentery, 17 were treated routinely, the remaining 27 were given sulfathiazole in addition to the routine treatment. The onset of the disease was approximately of equal severity in the drug treated and in the untreated (control) group. The first case occurred on Oct. 9, 1941, the last case on Dec. 30, 1941, and the three cottages were found to be entirely free from the Sonne organism for the first time on Feb. 26, 1942.

OBSERVATIONS

Table 2 shows the relationship of age to the incidence of the disease in the three cottages involved. It will be noted that in the youngest group (those from 6 to 10 years of age), 43 per cent became ill and 13 per cent were found to be carrying the Sonne organism without showing any abnormal symptoms. This may be compared to the group over 16 years of age in which only 6 per cent became ill and only 2 per cent carried the Sonne organism without symptoms. A similar relationship of age to susceptibility to bacillary dysentery has been pointed out by Davison,⁸ Quinlivan⁹ and Fyfe.¹⁰

A comparison is presented between the group receiving sulfathiazole and the group not receiving chemotherapy in table 3. The average age of the former group was about 11 years, while of the latter it was about 14 years. Statistically this difference was of no significance. The dose of sulfathiazole varied between 3 and 6 Gm. a day, depending on the weight of the patient, and was given in four to six doses a day for an average of four days. No evidence of toxicity due to the administration of the drug was encountered. As noted by others,¹¹ the average number of days of fever and diarrhea was less in the drug treated group, although the differences were small owing to the mildness of the disease. When only the cases of more than average severity were compared in the two groups, however, the beneficial effects of sulfathiazole were more appar-

ent. The clinical picture rapidly improved, while the duration of fever and diarrhea was definitely decreased.

The study of the weekly stool cultures in both groups was of considerable interest. In the control group, the average number of days from the onset of illness until the rectal cultures were consistently negative was 19.7 ± 3.7 (standard error) with a range from four to forty-eight days. In the sulfathiazole treated group, the number of days from the cessation of therapy until the rectal cultures became negative average 33.9 ± 4.4 (standard error) with a range from seven to eighty-four days.

Stool cultures during the administration of sulfathiazole, and for some days immediately thereafter, showed either no growth or an occasional colony of *Escherichia coli* on MacConkey's plates. However, in 20 of the 27 patients treated with the drug there was a return of the dysentery organisms within three weeks after treatment was stopped. Actually, 7 cases became positive during the first week, 10 additional cases during the second week and 3 during the third week. There were no relapses in the group not receiving sulfathiazole, while relapses occurred at varying intervals in 3 cases following the cessation of therapy in the drug treated group. One of the cases is of particular interest. This was a 12 year old boy who was admitted to the hospital on December 19 soon after the development of fever and diarrhea. Sulfathiazole was started on admission and continued for four days. The temperature and number of stools became normal within twenty-four hours after the drug was started, and the patient was returned to his cottage two days after the cessation of drug therapy. At this point rectal cultures showed no bacterial growth. Two days later his temperature rose to 102 F and numerous diarrheal stools were passed that were positive for *Bacterium sonnei*. Another four day course of sulfathiazole was administered and a rapid clinical recovery followed. Again the rectal culture showed no growth. One week later, however, the Sonne organism was again isolated. On Jan. 7, 1942, almost three weeks after his initial attack, he had, for the third time, diarrhea, fever and vomiting. He

TABLE 3—Comparison of Control and Sulfathiazole Treated Groups

Control	17	13.8 ± 2.6†	13 ± 0.2	29 ± 0.4	19.7 ± 3.7
Sulfathiazole treated	27	11.0 ± 1.3	10 ± 0.1	15 ± 0.2	33.9 ± 4.4

* 100 F or higher

† Standard error

received no drug therapy during this attack and was clinically well within forty-eight hours. Cultures taken at weekly intervals following this relapse remained negative. In the other 2 cases the relapses occurred five and eleven days, respectively after the cessation of drug therapy. Rectal cultures, which had shown no growth or only coliform bacilli following the cessation of drug therapy, again became positive for the Sonne organism. Additional drug therapy was not given and both patients made an uneventful recovery. In both cases rectal cultures became consistently negative fourteen days after their respective relapses.

During the study of healthy contacts in the institution, as well as the new admissions, 13 carriers of *Bacterium sonnei* were discovered. Ten of these harbored

the epidemic strain while 3 (the new admissions from the community) harbored a strain which differed from the epidemic strain by being rapid rhamnose fermenters

Six of the carriers were treated with 3 Gm of sulfaguanidine¹² a day for seven days, therapy being instituted within forty-eight hours after the first positive culture had been obtained. All but 1 remained well and failed on subsequent weekly cultures to show the dysentery organism, although they were followed for several months. The six, a carrier of the epidemic strain, received the usual dose of sulfaguanidine for seven days. Rectal cultures taken on the last day of therapy showed no bacterial growth on MacConkey's medium. Five days after the cessation of drug therapy, the clinical picture of dysentery developed with fever, diarrhea and vomiting. A rectal culture at this time was positive for the Sonne organism. He was treated with sulfathiazole and recovered clinically in forty-eight hours. Rectal cultures, however, remained positive for almost two months. This case is included with the sulfathiazole treated group.

That the sulfaguanidine contributed significantly to the clearing of the carrier state is doubtful in our cases because of the essentially similar course followed by the group of carriers that received no drug therapy. Of the 7 subjects in this group, 6 failed to show subsequent positive cultures after the organism was initially discovered, although rectal cultures were performed for almost two months. The seventh had consistently positive stool cultures for five weeks. At the end of this period he was given a similar course of sulfaguanidine. Subsequent positive cultures were not found following therapy.

The interesting feature of this phase of the study is the frequent occurrence of relatively short periods during which healthy carriers may harbor the dysentery organisms and thus serve as potential sources for the spread of the disease if not isolated. That the epidemic was spread in the institution by means of temporary carrier states in the relief personnel is not unlikely. Whether the prolonged carrier states would be benefited by sulfaguanidine remains to be seen. A recent study by Rantz and Kirby¹³ suggests that this may be the case. In that study, however, the organism isolated was identified as *Shigella alkalescens*.

An interesting observation was made in one of the uninvolved cottages during the latter part of the epidemic. Six hours after a lunch at which spaghetti and tomato sauce were served, 15 out of a total of 40 girls had severe cramps, diarrhea and vomiting, only a few had an elevation in temperature. Recovery was complete in from six to twelve hours. *Bacterium sonnei*, the epidemic strain, was isolated from a sample of the spaghetti. None of the affected children showed this organism in their stools, and a careful search failed to reveal any carriers among the personnel or unaffected inmates. Presumably contamination occurred prior to the cooking, which destroyed most of the viable organisms. One may speculate that a heat stable toxin may have been liberated from the organisms. The fact that the organisms were present in sufficient numbers so that they could be isolated from a random sample of the spaghetti is probably explained by the interval of

time that elapsed between the serving of the food and the subsequent examination which allowed the few remaining organisms to proliferate. Dysentery bacilli have been incriminated previously as a cause of food poisoning.¹⁴ The difficulty in tracing the source of these contaminations is well demonstrated by this experience.

COMMENT

Reports from Norway,¹⁵ Denmark,¹⁶ Scotland¹⁷ Germany,¹⁸ Canada¹⁹ and this country²⁰ indicate that *Bacterium sonnei* is the most frequent cause of dysentery in temperate climates. It has also been demonstrated that healthy carriers represent the most common means of spreading bacillary dysentery.²¹ The actual method of spread is usually the contamination of food, milk and water. Although it is not possible definitely to trace the source of the epidemic described here or the means of spread to three widely separated cottages, the frequent demonstration of relatively short carrier states in many of the healthy inmates makes it likely that the floating relief personnel might thus be implicated.

As previously noted, the clinical course of the disease in the control group was relatively mild. The routine use of sulfathiazole in the experimental group was primarily directed toward the possibility that by this means the carrier state following recovery from the disease might be considerably shortened and thus reduce the necessary period of isolation. Unfortunately this did not prove to be the case. Actually the Sonne organisms were demonstrated for much longer periods of time in the drug treated group than in the untreated controls. The complete isolation, or quarantine, of recovered cases is from a practical standpoint very difficult especially with young children in an institution. It is apparent, therefore, that the prolongation of the carrier state might add considerably to the problems of epidemic control under these conditions. While we were able to confirm the definitely beneficial effect of sulfathiazole on the clinical course of the disease, the adverse effect on the epidemiologic control should be appreciated. As a rule dysentery caused by the Sonne organism is a relatively mild disease. It would appear from this study that the routine use of sulfathiazole in institutional epidemics is not desirable. Its use, however, in selected cases is of undoubted value and a distinct contribution to the treatment of dysentery.

From an epidemiologic point of view the observation that, following the use of sulfathiazole the bacteriostatic effect of the drug may mask the presence of the dysentery organism should be stressed. In our cases, positive cultures reappeared as late as three weeks after the cessation of therapy. It would appear desirable to continue isolation for at least this period of time before negative stool cultures are considered significant.

CONCLUSIONS

In an epidemic of dysentery caused by *Bacterium sonnei* a method for obtaining rectal cultures yielded positive results in 43 of the 44 persons affected at the initial examination.

The use of sulfathiazole was associated with more rapid clinical recoveries as compared to the control group. However, in the former group there was a significant prolongation of the time required before the rectal cultures became consistently negative. Moreover, relapses occurred at varying intervals following chemotherapy, a complication that did not occur in the untreated group.

THE JUVENILE DIABETIC PATIENT
SURVIVING TWENTY YEARSH. E. EISELE, M.D.
ST. LOUIS

My purpose in this paper is to describe the physical, economic and social status of the juvenile diabetic patient surviving twenty years or more after the onset of the disease and to point out to the physician what he must look for, but not necessarily expect, in the life course of the diabetic child with onset of diabetes before his fifteenth year. The paper presents data on the first series of this kind to be reported. The data should present the most unfavorable picture which one will ever encounter in diabetes of this age group and duration because the children in the report lived in the preinsulin era at the time of the onset of the disease.

INCIDENCE

As shown in table 1, 1,685 juvenile diabetic patients were seen in this clinic between 1898 and March 1, 1942, of these, 1,363 were alive in 1941. Three hundred and twenty-two are dead, and 180 of these fatalities occurred before the use of insulin in 1922.¹ Of the total number of juvenile patients (1,685), 30 per cent had diabetes less than five years, 25 per cent between five and ten years, 25 per cent between ten and fifteen years and 15 per cent between fifteen and twenty years.²

Seventy-three patients with diabetes of twenty years' duration (i. e. until March 1, 1942) are the subject of report in this paper, they are 4.5 per cent of the 1,685 patients. Of the total number of patients (1,685) there were only 271 with onset prior to March 1922 and therefore eligible for a twenty year survival, and the 73 cases constitute 27 per cent of this figure. Among the juvenile diabetic patients with onset before March 1922 there were but 103 alive on that date, and the 73 represent 72 per cent of this number—a remarkable figure and far in excess of what one might expect.

The incidence and duration of juvenile diabetes in this series are divided into groups according to years of survival (five year periods). More striking, however, are the data for survival within relatively short

periods comprising the eras of Naunyn, Allen, Banting and Hagedorn. Duration of life for the juvenile diabetic patient in the earliest era was measured in periods of days or weeks and for those in the Allen era usually in one to two years, but as many as 72 of the 103 who were alive in March 1922 survived until the use of insulin was begun and 71 of these are alive today. Two members of this series have survived twenty years but are not living today, 1 died at the age of 29 with septicemia following an infection of the upper respiratory tract and the other, with a history of onset in 1886 at the age of 8 years died in coma twenty-nine years later, in 1915. The latter patient is the only 1 of the 73 with onset of diabetes prior to the year 1914.

The 73 juvenile patients are divided nearly evenly according to sex, 55 per cent being males. The average age at onset of the diabetes for this group is for the males 9.0 years and for the females 8.7 years. The youngest member of the group developed the disease at 1 year and 7 months and is now 21 years old, the oldest is 41, both are males. Of the entire group, 1 is living in the fifth decade of life, 39 are in the fourth decade and 31 in the third decade.

The average duration of the disease is 21.9 years, which means that the average patient of this group was without insulin 2.8 years of his diabetes, if one figures that insulin became available to most of these patients by January 1923.³ The highest incidence of a positive hereditary history (save in homologous twins, in which it is 63 per cent) is in the group of this age and duration namely, 62 per cent. The proportion of the Jewish population in this series is 10 per cent, which is approximately equal to that among all of the juvenile diabetic patients.

TREATMENT

Treatment with insulin is divided among the 71 living patients today, so that 69 are taking an average of 52 units of insulin of either single or combined types. Twenty-five use regular or crystalline insulin alone (average 47 units), 12 use protamine zinc insulin alone (average 47 units), 31 use combined protamine zinc and crystalline insulin (average 13 units of crystalline insulin plus 47 units of protamine zinc insulin) and 1 takes 60 units of globin insulin.

The majority, 51, are on weighed diets, 20 are on free diets by their own choice, but few if any take indiscriminately foods high in carbohydrate value.

Two patients who are taking no insulin at all are under observation because of the possibility of a "cure" or "remission" of the disease. One was first seen in this clinic in 1922 at the age of 16, two years after the onset of her diabetes. Her family physician reported a blood sugar value of 340 mg. per hundred cubic centimeters, a large amount of urinary sugar and a Van Slyke plasma carbon dioxide determination of 22 volumes per cent, this was associated with an infection at the age of 14. Two years later her blood sugar tolerance curve was not diagnostic of diabetes, and her urine contained 1.3 per cent sugar. She was put on a restricted diet, and in repeated examinations of her blood since her first visit the blood sugar value has at times been elevated but never high enough for a diagnosis of diabetes. The second patient with a question of a "cure" is a 39 year old man who had shown glycosuria intermittently since the age of 14 and because of an abnormal blood sugar curve was denied insurance,

3. Of these children only 23 received insulin in this clinic prior to March 1923.

Dr. Eisele was fellow in the George F. Baker Clinic, New England Deaconess Hospital, Elliott P. Joslin, M.D., Medical Director.

1. The date on which the first patient, an adult, in this clinic received insulin was Aug. 7, 1922.

2. A detailed analysis of the complications and treatment of 150 juvenile diabetic patients of this series who had survived fifteen years of diabetes in 1939 has been given (Joslin, E. P., Root, H. F., White, Priscilla, and Marble, Alexander, *The Treatment of Diabetes Mellitus*, ed. 7, Philadelphia: Lea & Febiger, 1940, p. 687). For the accumulation of much of the data presented in this paper I am indebted to Dr. Priscilla White.

this brought him to the clinic in 1938. A dextrose tolerance test afforded a comfortable diagnosis of diabetes mellitus, and he was placed on a moderately restricted diet. At present the sugar tolerance curve is not diagnostic for diabetes, the highest blood sugar level was 160 mg per hundred cubic centimeters following 100 Gm of dextrose when fasting.

PHYSICAL STATUS

The gross physical development of the diabetic child plays a major role in the complications of this disease, and in this group 13 persons, 1 out of 6, were classified some time during their lives as dwarfs, almost twice this number fell in the category of infantilism. Treatment consisted of pituitary and thyroid supplement, however, the first treatment began late in adolescence, and some of these retain juvenile proportions. The gross physical status today is described in table 2.

COMPLICATIONS

Further tabulation of the physical findings reveal that 35 per cent have an enlarged liver.⁴ The criterion for such a diagnosis is a liver palpable 3 fingerbreadths below the costal margin in the midclavicular line. Thirty per cent of those examined showed evidence of arteriosclerosis at an average age of 29, as demonstrated by x-ray examination of the extremities. At present, one half of these patients showing peripheral arteriosclerosis have albuminuria and blood pressure greater than 150 systolic and 90 diastolic. Ocular lesions are common, and 55 per cent of those examined have moderate to advanced retinal arteriosclerosis, 42 per cent show hemorrhages and 32 per cent exudates, 16 per cent have ocular cataracts. The blood pressure is greater than 150/90 in 20 per cent of the group. If one considers together all the patients with demonstrable arteriosclerosis, either retinal or peripheral or both, 70 per cent of them have findings indicating more advanced cardiovascular-renal changes, as indicated by the presence of either hypertension or albuminuria or both.

Diabetic coma has appeared at least once in 21 of the 73 patients. One patient has been in coma sixteen

TABLE 1—Status of Diabetic Children Seen Between 1898 and March 1, 1942

	Total	Living	Dead
Naunyn era 1898-1914	84	0	84
Allen era 1914-August 1922	266	81	185
Banting era August 1922-December 1933	951	845	106
Hagedorn era January 1936-December 1941	444	437	7
Totals	1650	1363	287

times. Psychiatric problems are classified under two main headings, psychoneurosis and depression. There are 5 patients with the first condition and 3 with the second. Each of the 3 with mental depression has made at least one attempt at suicide. Infections include chiefly cutaneous lesions in the form of carbuncles or abscesses, and one third of this group have been afflicted at some period. Lesions of the teeth or gums very infrequently offer serious complications, 85 per cent have dental caries and 45 per cent have pyorrhea. Other lesions and complications, representing 1,553 diabetic years, may be listed: peripheral neuritis 7, retinitis proliferans 2, atrophy of the optic nerve 2,

necrobiosis lipoidica diabetorum 1, calcinosis 1, pleurisy 1, chronic glomerular nephritis 2, mastoiditis 1, nocturnal diarrhea 1, asthma 1, osteomyelitis 1, intermittent claudication 1, ovarian cyst 1 and active recent pulmonary tuberculosis 1. That more of these patients with juvenile diabetes of long duration do not harbor tuberculous infections does not indicate that contrary to the rule they are relatively resistant to the acid fast organism but implies that these particular ones have survived merely because they have been fortunate enough to escape tuberculosis.

Operative procedures have been done with little if any increased hazard and they have included removal

TABLE 2—Gross Physical Status of Juvenile Patients Surviving Twenty or More Years

	Least	Height Greatest	Average	Least	Weight Greatest	Average
Female	4 ft 10 in	5 ft 9 in	5 ft 4 in	100 lb	135 lb	110 lb
Male	5 ft 1 in	6 ft 2 in	5 ft 7½ in	100 lb	175 lb	140 lb

of tonsils and adenoids, excision of pilonidal cyst, five cesarean sections, four appendectomies, a spinal fusion, mastoidectomy, removal of a rectal polyp, a low leg amputation and a low thigh amputation.

EDUCATION

The educational achievement is probably the most striking feature brought out in this study. College was attended by 31 of the group (42 per cent) and 4 have gained academic honors as measured in terms of awards, honorary degrees or membership in scholastic fraternities. These figures are remarkable in view of the fact that only 7 per cent of Americans 21 years of age and over in 1934 had attended college. Evaluation of the figures for this group, of course, must be made in the light of the patients' financial, familial and environmental circumstances. This group may be divided into four economic categories which probably best connote the most important influences for advancement and survival: (1) the distinctly wealthy in which there are 10 members, 80 per cent of whom attended college; (2) the professional and those with moderate incomes, 28 members, 53 per cent of whom attended college; (3) those with low incomes, 13 members, 30 per cent of whom attended college; and (4) the underprivileged, 22 members, 18 per cent of whom attended college.

ECONOMIC AND SOCIAL STATUS

Utilizing the same classification and division of patients of this series, one sees that the control of diabetes parallels the economic level, as may be surmised. The incidence of complications is highest in the underprivileged group and lowest in those who are from wealthy families. However, there are individual exceptions, some in the lowest income group show little or no complications, while others in the upper brackets show moderate to fairly advanced complications.

The economic and social status of these juvenile diabetic patients is important, as far as the treatment is concerned, both to the patient and to the physician. The occupations which they follow for a livelihood are certainly as extensive and varied as those of any group of nondiabetic patients. The list includes merchants, secretaries, laborers, an artist, clerks, housekeepers, salesman, a comptometer operator, an accountant, a teacher, a journalist, a comparison shopper, a medical

⁴ The further analysis of causes and treatment of hepatomegaly is given by Joslin, Root, White and Marble. Treatment of Diabetes Mellitus, p. 472.

⁵ Personal communication from U. S. Office of Education.

student, a lawyer, a cashier, an electrical engineer, an advertisement agent, a reporter, a merchant marine radio operator and laboratory technicians

Married members of this group number 30, 13 are men, 17 are women. Two persons are twice married. There are a total of 35 living and as far as we know, healthy children from this group, 16 of these are children of 10 juvenile diabetic women, 3 of whom had clinical toxemia of pregnancy. Two children are known to have congenital anomalies, one hydrocephalus and the other syndactylism. These figures for congenital anomalies are probably low, however, in view of the known high occurrence of such conditions in offspring of diabetic patients.

CONCLUSIONS

Bearing in mind that all these 73 juvenile patients developed diabetes before insulin became available and accordingly present physically the worst possible end results for this age group and duration, certain conclusions are permissible.

1 The most important complication is the early appearance of arteriosclerosis. Thirty per cent of the members of this series who were examined roentgenologically showed peripheral arteriosclerosis, 55 per cent showed moderate to advanced ocular arteriosclerosis. Seventy per cent of the patients showing these changes have either hypertension or albuminuria or both at an average age of 29 years.

2 Impaired physical development in childhood occurred in 16 per cent of this series. With present day diabetic control and endocrine therapy this problem becomes much less acute than formerly. The physical status of the average adult in this series appears favorable even though active supplementary endocrine treatment in addition to insulin was started relatively late in the development of those physically retarded. The average male adult weighs 146 pounds (66.2 Kg) and stands 5 feet 7½ inches (171 cm), the average woman weighs 127 pounds (57.6 Kg) and stands 5 feet 4 inches (163 cm).

3 Sex does not influence survival. The disease was hereditary in 62 per cent. Mental maladjustments are somewhat greater in the juvenile diabetic patient than in the nondiabetic person of this age.

4 Infection has played a relatively minor role. Operative procedures may be done with little increased hazard over that in a nondiabetic group.

5 Like the older patient, with onset of diabetes in adult life, the juvenile diabetic patient has a constantly improving outlook for life and good health with the present day method of diabetic control and refined medical and surgical treatment.

6 The educational achievement of those who make up this series is probably the most striking feature brought out in the study. 42 per cent have attended college, as compared to 7 per cent of the population of the continental United States who are 21 or more years of age. The positions attained in economic and social life are not materially different from those in a similar group of persons of this age who do not have diabetes.

7 A woman's chance for a healthy child after twenty years of diabetes with onset in childhood is becoming increasingly more favorable.

OCULAR CHANGES IN YOUNG DIABETIC PATIENTS

C. S. O'BRIEN, M.D.

AND

J. H. ALLEN, M.D.

IOWA CITY

Ocular complications of diabetes mellitus are believed to be extremely rare in patients under 35 years of age. In fact, until recently ophthalmologists were under the impression that one never encountered diabetic retinopathy in these younger persons. It is now recognized that cataract is not infrequently seen in children and young adults with this common metabolic disease. Also changes in refraction are common, especially at times when the blood sugar concentration is changing rapidly. As proof that diabetic retinopathy is not so rare as generally believed studies of the fundi of 555 young patients with diabetes revealed 23 with retinal pathologic change which was apparently due to that disease alone. Also in an additional survey of 260 young diabetic patients 43 were found to have lens changes of the type known to occur with this disease. In our experience there are two very rare ocular complications of diabetes, namely hypemia retinalis and lowered intraocular tension accompanying acidosis.

TABLE 1—Lens Changes in 260 Diabetic Patients Under 21 Years of Age

Diabetic cataract	20
Congenital lens changes	191
Punctate opacities	183
Vogt's coronary cataract	6
Other types	2
Fraunhofer cataract (unilateral)	1
Congenital pigment dots on lens	12

DIABETIC RETINOPATHY

Twenty-three cases of diabetic retinopathy were encountered in a survey of the fundi of 555 diabetic patients under the age of 31 years. This is an incidence of 4 per cent (table 2). In the majority of these cases the retinal lesions consisted of hemorrhages and degenerative areas similar to those found in early cases of diabetic retinopathy in older patients. The hemorrhages usually were punctate, but occasionally they were of the small striate variety. Both types occurred most frequently in the perimacular region or in the region of the temporal vessels. Small, hard, waxy, yellowish white areas of degeneration were seen in the central portion of the fundus in 10 cases, and cotton wool patches were observed along the course of the temporal vessels in 7 cases.

In 6 of the 23 cases of retinopathy the changes were transitory, they were observed after a period of six months to one year of poor control and disappeared within one to two months after strict control was instituted. Four of these patients showed only punctate hemorrhages, 1 was found to have edema of the nerve heads and hemorrhages, and the last exhibited cotton wool patches and hemorrhages.

Additional findings were noted in 3 cases. An 11 year old girl, the subject of a previous report by Allen

From the Department of Ophthalmology, State University of Iowa College of Medicine.
Read before the Section on Ophthalmology at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

and Howard,¹ had not only retinal hemorrhages but a well developed lipemia retinalis. Another patient, a 14 year old girl, had retinal hemorrhages and later developed edema of the nerve heads. This child had had diabetes for eleven years and control had never been good, but in the year preceding the development of the fundus condition management had been neglected. Complete medical and neurologic examinations failed to reveal any other cause for the retinopathy, and ophthalmoscopic examination made after three months of rigorous control revealed normal fundi. A third patient, a 22 year old man with chronic mastoiditis and peripheral neuritis, gave a history of diabetic symptoms of four years' duration without treatment. Ophthalmoscopic examination disclosed many punctate and several striate hemorrhages and a few cotton wool patches in each fundus. After nine months of poor control, reexamination of the fundi revealed numerous hemorrhages, occlusion of the central retinal vein in the left eye and a proliferating retinopathy in both eyes

in coma with a blood sugar of 633 mg per hundred cubic centimeters. The fundi showed punctate hemorrhages, areas of hyaline degeneration and a few cotton wool patches. Later hypertension developed and there was albumin in the urine. Eventually edema of the nerve heads and retina appeared in each eye, also many punctate hemorrhages and areas of hyaline and cytoid degeneration were seen.

DIABETIC CATARACT

In 1934 O'Brien, Molsberry and Allen² reported the incidence of lens changes in diabetic patients under 33 years of age as 16 per cent. The present study of cataracts in association with diabetes was made on 260 consecutive patients under 21 years of age. As in the previous survey,² the patients were observed at intervals of three or four months over a period varying from two to eight years, and diabetes was considered to be the cause of the lens changes only in those cases in which the opacities were of the snow-

TABLE 2—Fundus Changes in 555 Diabetic Patients Under 31 Years of Age

Kidney function was normal in all cases

† Lipemia retinalis

§ Thrombosis of central vein left eye Proliferative retinitis both eyes

* In milligrams per hundred centimeters on actual load

† Choked disk

Repeated general examinations disclosed no other cause besides diabetes, the blood pressure varied between 112 systolic and 68 diastolic and 132 systolic and 78 diastolic and kidney function tests were normal.

In addition to the 23 cases of diabetic retinopathy, 2 young diabetic patients who also suffered from hypertension and nephritis were found to have advanced retinal pathologic changes. In one of these, a 20 year old girl who had had diabetes for seventeen years, the blood pressure was elevated and the urine contained albumin as well as sugar. The fundi showed punctate hemorrhages and areas of hyaline degeneration in the macular regions. This patient's general condition and her eyes gradually grew worse until at the end of one year the vision was 6/60 in both eyes and the fundi showed advanced neuroretinopathy—the nerve heads and surrounding retina were edematous, the arterics were reduced in caliber, the veins were engorged, beaded and tortuous, and there were many retinal hemorrhages and areas of hyaline and cytoid degeneration. The other patient, a 21 year old man, had been diabetic for thirteen years. He was admitted

flake or the subcapsular varieties and in which there was definite increase in the opacities.

In this group of 260 patients there were 36 with diabetic lens changes an incidence of 13.8 per cent (table 1). In 3 patients the cataracts required extraction and in 10 others the lens changes resulted in some loss of visual acuity. In each case in which diabetic cataracts were found the diabetes had been poorly controlled or uncontrolled for several months or years preceding the development of lens changes. In 6 cases the lenses were clear when first examined but on reexamination after periods of one to two years of poor control or noncontrol, snowflake opacities or fine subcapsular plaques were observed. In these cases rigorous control was instituted and, although some increase in the number of opacities was observed for a few months, further increase was not seen after six months. In 5 other cases arrested development of opacities was observed after six months of strict control. However, in 7 cases adequate control of the diabetes could not be obtained at home and the number of lenticular opacities has continued to increase.

CHANGES IN REFRACTION

Several authors have reported transitory changes in refraction in young diabetic patients. These have been manifested by the development of a relative myopia during periods of poor control and the development of a relative hyperopia during reduction of the blood sugar level with insulin. In 12 patients ranging from 8 to 28 years of age, previously untreated, the authors did daily refractions under scopolamine for ten to fourteen days after the institution of insulin therapy. A relative hyperopia of 1.00 to 3.00 diopters developed within three to five days after insulin was begun but disappeared within seven to ten days.

COMMENT AND CONCLUSIONS

Certainly the most interesting and striking feature of this study of the eyes in younger diabetic patients is the incidence of retinopathy—4 per cent in a series of more than 500 cases. The retinal disorder must be attributed to the diabetes, since it has the same appearance as that occurring in older patients and it is seen in those in whom no other disease can be found. It is a foregone conclusion that such ocular changes were not observed a few years ago. This is probably due to the fact that until recently young people with diabetes lived a comparatively short time. At present, while we do not cure diabetes, the control of the disease is infinitely better and the patients live much longer, therefore the retinal changes have a chance to develop.

As far as lens changes are concerned, this study only confirms the fact that diabetic cataract is comparatively common—in this study an incidence of almost 14 per cent in 260 patients under the age of 21 years.

ABSTRACT OF DISCUSSION

DR GLEN GREGORY GIBSON, Philadelphia. Drs O'Brien and Allen have again called attention to the ever increasing responsibility which ophthalmologists must assume in the field of internal medicine. In view of the relatively rapid progressive changes which are occurring today in the practice both of internal medicine and of ophthalmology it becomes necessary that we assume an equally progressive point of view when the evidence is sufficiently convincing to warrant it. This paper is the result of the combination of progress in internal medicine in the form of the treatment of diabetes by insulin and careful clinical research in medical ophthalmology over a period of many years. The section is fortunate in having these authors bring to us the benefits of their extensive experience and studies in this most important subject. They stressed the increasing incidence of diabetic retinopathy in the younger persons, and I am in complete accord with their findings and explanation of these changes in the retinas of young persons with diabetes. It seems that this paper, in addition to many other excellent contributions by other authors, would once and for all put an end to that school of thought which denies the existence of a specific retinopathy that is pathognomonic of diabetes mellitus. Diabetic retinitis rather conveniently divides itself into a working classification of the well known central punctate type, the diffuse type, the mixed diabetic and hypertensive type and the venous type, any one of which may progress to retinitis proliferans and any one of which is usually sufficiently characteristic to permit an ophthalmoscopic diagnosis of diabetes. The case histories in this paper include examples of each of these types of retinopathy. It is well known that the conditions under discussion are not only resistant to treatment but, even under an adequate diabetic regimen as we know it today, are particularly prone to be progressive. Therefore it is encouraging to learn that in 6 of their 23 cases the retinopathy was transitory. This is consistent with the claims of our diabetic department that these retinal changes do not develop in the cases which are recognized sufficiently early and in which cooperation in the medical regimen is adequate.

This would tend to increase our interest in demanding adequate medical management of these cases, particularly the early ones. The authors have also found evidence of the other well known ocular complication of diabetes in their younger patients, such as lipemic retinitis, hypotension, refractive changes and cataracts. Our experience has been similar with the exception of the incidence of cataracts in these young diabetic patients. In spite of careful search for these changes, we have been unable to detect them in any such frequency as they report in two series, namely 16 and 13.8 per cent. This paper has been of real value because it calls attention to the necessity of careful study of the younger as well as older diabetic patients and because it stresses the necessity of a rigid diabetic regimen for patients with this disease.

ARTERIOSCLEROSIS WITH DIABETES
MELLITUS

A STUDY OF THE PATHOLOGIC FINDINGS IN
193 DIABETIC AND 2,250 NONDIABETIC
PATIENTS

JAMES R. LISA, MD
MORTON MAGIDAY, MD
IRVING GALLOWAY, BS

AND
JAMES FINLAY HART, MD
NEW YORK

Diabetes mellitus is generally considered an influence in the production of arteriosclerosis. Joslin was one of the earliest believers in the relationship and has persistently stressed its seriousness. Root and his associates,¹ Warren² and Wilder,³ among others, have presented abundant affirmative evidence. Our interest in the problem was to determine the extent and degree of arteriosclerotic changes in the diabetic patients who came to autopsy at New York City Hospital, Welfare Island, and note if our conclusions supported the present belief.

The material observed consisted of 193 patients with diabetes mellitus who came to autopsy between Jan. 1, 1928 and Dec. 31, 1941. Because the observations in a few of these cases were not complete, the figures in the subsequent data do not always correspond with the total number of cases observed. Only data on patients 40 years or over were included. Subdivisions were made relating to (1) coronary arteries, (2) aorta, (3) size of the heart, (4) state of the cerebral arteries, (5) presence or absence of arteriolar disease of the kidneys compatible with hypertension and (6) comparison of the visceral and peripheral arteriosclerotic changes in patients with amputations coming to autopsy. As a control we used the findings in approximately 2,250 nondiabetic patients who came to autopsy in the hospital during the same period.

Among the diabetic there were 87 men and 106 women. Although the great majority were white persons, there were a few Negroes. However, since race had no bearing on the findings, such a distinction was disregarded in the final analysis.

From the Pathological Laboratory and the Metabolic Service of the Medical Divisions, New York City Hospital, Welfare Island.

³ Wilder R. M. Clinical Diabetes Mellitus and Hyperinsulinism. Philadelphia. W. B. Saunders Company. 1940.

The type of arteriosclerosis was no different in the diabetic patient than in the nondiabetic, and, furthermore, sclerotic changes of equal severity were found in both groups.

We have considered the possibility of error in our study. First, this hospital is a general hospital with no more than the usual incidence of diabetes (18 per cent). There is no emphasis put on this disease, and hence there is no greater search for arteriosclerosis in this group than in the controls. Furthermore, we have disregarded in our statistical comparisons any differences which may have arisen as a result of chance variation as determined by a common statistical test and have given full realization to the possibility of fallacious reasoning from percentages in those subdivisions with only a few cases.

PATHOLOGIC FINDINGS

In each of the subdivisions it was found that arteriosclerosis was more frequent in the diabetic than in the nondiabetic patients. Arteriosclerosis, however, is a disease associated with old age, making it necessary to adjust our percentages in consideration of any age differences which may exist in the composition of the two samples. This step assumes added significance in view of the fact that the average age in the diabetic group is 63, while that in the nondiabetic group is 61, two years less. As a further precaution the data were analyzed according to decennium of age. This served the added purpose of exposing any possible age relationship.

Considering coronary arteriosclerosis first, we noted that it was more frequent among those with diabetes than those without. In this group were analyzed the pathologic findings of 193 diabetic and 2,092 nondiabetic patients. As shown in table 1, the "corrected" frequency of arteriosclerosis among diabetic patients was

TABLE 1—The Frequency of Arteriosclerosis in Diabetic Persons Compared with That in Nondiabetic Persons

	Patients with Arteriosclerosis							
	Number of Persons Studied		Percentage					
			Number		Crude		Corrected*	
	Diabetic	Nondiabetic	Diabetic	Nondiabetic	Diabetic	Nondiabetic	Diabetic	Nondiabetic
Coronary arteries	193	2,092	138	1,202	72	60	70†	60†
Aorta	162	1,976	143	1,974	79	70	76	70
Cerebral arteries	51	557	33	313	65	56	56	56

Cardiac infarction	138‡	1,202‡	42	280	30	22	39†	22†

* Corrected for differences in the age distribution of the two samples using as a standard the age composition of the entire group of cases observed.

† These differences are significant by the chi square test and the probability that they may be due to chance is very small.

‡ The patients studied in these groups all had arteriosclerosis.

70 per hundred, as compared with 60 per hundred among the nondiabetic patients. Among the diabetic patients with arteriosclerosis, moderate changes were found in 35 per cent and severe changes in the other 65 per cent, while among the nondiabetic patients with arteriosclerosis moderate changes occurred in 48 per cent and severe changes in 52 per cent (table 2). This attested the more severe nature of the arteriosclerosis in the presence of diabetes.

Division into ten year age groups brought out further evidence of the greater frequency of severe coronary arteriosclerosis among the diabetic than among the nondiabetic, and in tables 3 and 4 it may be seen that in all age groups severe coronary arteriosclerosis was more common among the diabetic patients.

TABLE 2—Comparison of the Severity of Arteriosclerosis in Persons With and Without Diabetes

	Persons With Diabetes		Persons Without Diabetes	
	Number	Per Cent	Number	Per Cent
Coronary arteries				
Involved	138	100	1,202	100
Severe	90	65	606	50
Moderate	48	35	596	49
Aorta				
Involved	143	100	1,974	100
Severe	90	63	1,000	45
Moderate	53	37	974	55
Cerebral arteries				
Involved	33	100	313	100
Severe	26	79	160	60
Moderate	7	21	153	49

Cardiac infarction with or without coronary thrombosis was next considered. There were 42 diabetic and 280 nondiabetic patients with cardiac infarcts. Since practically all of them had moderate or severe coronary sclerosis, our percentages describe the incidence of cardiac infarction in the group with coronary sclerosis. It will be seen that cardiac infarction also was more common in the diabetic patients (30 per cent versus 22 per cent). This is further evidence of the more serious nature of arteriosclerotic changes in the presence of diabetes.

In tables 3 and 4 it is seen that although in both diabetic and nondiabetic patients the frequency of coronary arteriosclerosis increases as age advances, the incidence of cardiac infarction is not affected by age. At all ages, to be sure, its frequency was greater among the patients with diabetes.

The condition of the aorta was analyzed in 182 diabetic and 1,976 nondiabetic patients. The data closely resemble those for the coronary arteries, the aorta likewise showing a higher rate of sclerotic changes in the diabetic patient than in the nondiabetic one (76 per hundred versus 70 per hundred). This difference, however, may be due to chance, but in the groups with severe involvement the differences between the diabetic and the nondiabetic patients are significant.

The size of the heart was noted, but the data showed little of importance. The information was obtained from 178 diabetic and 2,104 nondiabetic patients. There were numerous hearts of comparatively low weights, but many of these came in the senile age period and were probably the result of senile atrophy.

The analysis of the cerebral arteries could unfortunately, be based on only 51 diabetic and 557 nondiabetic patients. Differences between the two groups were statistically not significant and are therefore dismissed without further comment.

The kidneys were examined microscopically for the presence or absence of arteriolar sclerosis compatible with hypertension. No distinction was made between arteriolar nephrosclerosis and arteriolar disease found in cases of pyelonephritis. The analysis was based on 184 diabetic and 2,050 nondiabetic patients. Arteriosclerotic changes in the kidney compatible with hyper-

tension were much more common in the diabetic than in the nondiabetic patients ("corrected" rates 63 per hundred versus 50 per hundred), and greater frequencies existed at all ages for those with diabetes

It was possible to compare the peripheral vascular tree and the visceral arteries in 17 diabetic and 9

without. Hence we add further confirmation to the present belief that diabetes is a factor in the production of sclerotic changes in the arteries

COMMENT

We must differ with Wilder in his statement that sclerotic changes occur no more frequently than usual in persons with diabetes. Our data unquestionably show that arteriosclerosis, especially in the severe form, appears more often in the diabetic patient at practically all ages. Under these circumstances we must disagree with his argument that an equal occurrence of arteriosclerosis proves that diabetes of and in itself is not a cause of arterial disease. We can nevertheless accept his suggestion that diabetes probably hastens the development and speeds the course of arterial changes.

We are unable to consider the effect of the degree of severity or the duration of the diabetes, as the records were incomplete in many of our cases. These factors were studied by Root and Sharkey, and because they found such a high incidence of coronary thrombosis in persons 70 years or over with mild diabetes of long duration they concluded that the duration of the diabetes meant more than the age of the patient or the severity of the disease.

From table 5 we must conclude that arteriosclerosis appears earlier in the diabetic than in the nondiabetic

nondiabetic patients. Each of these had an amputation for peripheral occlusive disease. Two facts were evident. Amputations were done among the diabetic in practically equal numbers in the seventh and eighth decades, 8 and 7, respectively. Only two amputations were performed in the sixth decade, the 2 patients having severe cellulitis. In the nondiabetic group 8 of the 9 patients with amputations were in the seventh decade. The second observation was that almost without exception those with diabetes had arteriolar disease of the kidney compatible with hypertension (15 out of 17). Among the nondiabetic patients the opposite almost invariably held true. Of the 9 nondiabetic persons only 1 had arteriolar sclerosis. The degree of visceral changes was more closely parallel to the renal arteriolar sclerosis than to the peripheral vascular changes.

We have shown in a previous communication⁴ that the peripheral sclerosis was of equal severity in diabetic and nondiabetic patients. The coronary and aortic sclerosis in the diabetic group was almost invariably severe, with only 2 patients having the moderate form and 1 who was normal. In the nondiabetic group they were about equally divided.

Our findings give us unquestionable evidence that, in general, arteriosclerosis is more common and more frequently severe in persons with diabetes than in those

patients. The original series of 193 patients with diabetes and 2,092 without diabetes showed coronary involvements in 138 of the former and 1,252 of the latter.

In patients in the fourth decennium we found sclerotic changes in 57 per cent of those with diabetes. So high an incidence in the nondiabetic group was not reached until well into the fifth decennium, more than ten years later. Tables 3 and 4 present additional

4 Lisa J. R. Magid, Morton and Hart J. T. Peripheral Arteriosclerosis in the Diabetic and the Nondiabetic. A Study of One Hundred and Six Amputated Legs. J. A. M. A. 118: 1353 (April 18) 1942.

evidence of the greater frequency of sclerotic changes, especially in the severe form, in the early ages of the diabetic patients. This tends to support the contention of Joslin that diabetes is a factor in the production of arteriosclerosis and that sclerotic changes will be produced at an earlier age in the diabetic than in the nondiabetic patient.

It is doubtful whether the higher incidence of, or earlier appearance of, sclerotic changes in the diabetic person can be attributed to any new factor. It seems more likely, whatever the factor or factors causing arteriosclerosis, that diabetes influences its development and severity. This possibility is further strengthened by the fact that we found no difference in the type of arteriosclerosis in the groups in this study or in an earlier investigation of the peripheral arteries.

TABLE 5—The Percentage Frequency of Sclerotic Changes by Age Groups

Age	Arteriosclerosis	
	Diabetic Patients	Nondiabetic Patients
40-50	57%	31%
51-60	60%	53%
61-70	77%	69%

81-90	86%	82%
91 and over	100%	78%

SUMMARY AND CONCLUSIONS

Arteriosclerosis is more common in diabetic than in nondiabetic persons.

Arteriosclerosis is more frequently severe in diabetic than in nondiabetic persons.

Severe arteriosclerosis is more frequent among persons with diabetes at all ages.

Sclerotic changes in both the diabetic and the nondiabetic person increase in frequency as age advances, but among persons with diabetes a given frequency of these changes is reached about ten years earlier than among those without the disease.

Occlusive accidents in the coronary arteries occur with greater frequency among diabetic than among nondiabetic patients at all ages, but the frequency of such accidents is not correlated with age.

Arteriosclerosis of the kidneys compatible with chronic hypertension is more frequent among diabetic than among nondiabetic patients.

Peripheral arteriolar sclerosis necessitating amputation is of equal severity in persons with and without diabetes. It has no close relationship to visceral arteriosclerosis, but the severe visceral changes are much more frequent in diabetic persons.

Clinical Notes, Suggestions and New Instruments

SIMPLIFIED METHODS FOR THE ADMINISTRATION OF BLOOD PLASMA IN EMERGENCIES

LOUIS K. PITMAN, M.D., NEW YORK
Associate in Otolaryngology, Beth David Hospital

Normal human blood plasma is a satisfactory substitute for whole blood in the treatment of certain conditions such as shock with or without hemorrhage, burns and the restoration and maintenance of body proteins and in the emergency treatment of severe hemorrhage. It has the advantage of not undergoing progressive changes or requiring typing or cross matching.

The usefulness of blood plasma is enhanced when it is prepared in powder form by the lyophilic process so that it can be stored a long time without deterioration.

As available on the market, powdered blood plasma is packed in an ampule vial, accompanied by a bottle containing 250 cc of sterilized distilled water. When the two are mixed they yield the original volume of the untreated blood plasma. This solution is effected by means of a double pointed connecting needle, one point of which is inserted manually through the stopper in the vial of distilled water and the other end through the stopper of the vial of plasma. Since the plasma is vacuum packed, the negative pressure of the vial draws in all the distilled water.

In a few minutes the plasma is restored to the fluid state. The needle is then withdrawn from the stopper of the plasma vial.

To administer this restored plasma the vial is inverted in a hollow canister so that its neck projects slightly from the bottom. The needle of an air filter assembly is then inserted diagonally through the rubber stopper of the vial while the filter end is attached over the upper edge of the canister. The needle connecting the stylet of the intravenous equipment is inserted through the rubber stopper of the vial diagonally and in opposite direction to the air filter needle. The air is now displaced in the entire intravenous equipment.

The intravenous needle is then ready to be inserted into the vein, the flow of the plasma being regulated by a screw clamp.

While it is simple to set up the apparatus in an operating room under strict aseptic conditions

it is not easy, as this brief description indicates, to do so under emergency conditions, as on a battlefield. There are too many parts to be adjusted, too many needles to be exposed and too much work to be done. Under adverse conditions it would be difficult to maintain sterility.

In order to simplify the procedure, I have devised an apparatus which eliminates much of the manipulation required by

Fig. 1—Suspend bottles by wire. Attach water bottle to steel device with relation to plasma bottle. Shut screw clamp S. Mechanically introduce needle B through rubber stopper C and likewise needle B through stopper C. Let air into two bottles by mechanically puncturing stoppers 4 and 4' with open needles already in place. Water will enter plasma bottle causing plasma to dissolve. Let air escape from intravenous tube. Introduce needle into vein. Regulate flow by screw clamp S.

At the Center of the Sun—Atomic energy feeds the sun, consuming hydrogen and ending with helium, with carbon playing the part of go-between, said H. A. Bethe, professor of physics at Cornell University, in a Sigma Xi lecture at the Illinois Institute of Technology, March 25, 1942. The sun would last another thirty billion years if it continued to expend its energy at the present rate, but the sun becomes hotter and more extravagant as it eats up its hydrogen, and probably will not last more than ten billion years. The temperature at the center of the sun is 20 million degrees C according to the theories of Eddington, Stromgren and others. Because of the high temperature, the nuclei which are the central cores of atoms with a diameter less than one ten thousandth that of the atom are rushing about furiously, knocking each other to pieces and recombining to form a new atom or element, or an unstable nucleus may be formed and shortly blow up. On each of these occasions there is an evolution of energy in the form of radiation. It is this that feeds the sun.

the kind now in use. It consists of two bottles clamped together, as shown in figure 1. One contains sufficient powdered plasma to yield 250 cc of fluid plasma when restored to its original volume, the other enough sterilized distilled water. The distilled water bottle is adjusted to a higher level. Each bottle has an additional outlet opposite the mouth, both outlets being sealed by rubber diaphragms. A threaded cap fits over the mouths of the bottles. Circulation of the fluid is achieved by means of a Y tube fitted with needles (B and B') at the forked stems and an intravenous needle at the distal stem of the Y. A screw clamp (S) shuts off or regulates the flow of plasma entering the vein.

The procedure of administering the plasma is as follows:

- 1 The screw clamp (S) is tightened (fig. 1)
- 2 Needle B is forced mechanically through diaphragm C into the plasma bottle as described in the legends of figures 1 and 2, and needle B' is forced through diaphragm C' into the distilled water bottle, in like manner
- 3 Air is let into the two bottles by puncturing the diaphragms of the upper stoppers (A and A') mechanically with open needles fitted with air filters at its mouth. To seek its own level the water being at a higher level, will enter the plasma

Fig. 2—The threaded cap (T) fits over the mouth of the bottle (K) on which it is only partially screwed when stored. This cap is drilled so that it can be slipped on over the needle (B) which is inserted first and is fixed in position by a metal washer (R) on its shank. The tip of the needle rests in the channel of the stopper. To puncture the diaphragm the cap is screwed on forcing the needle against it as shown in the diagram at the right.

bottle through the unobstructed channel of the forked stems of the Y tube, dissolving the plasma.

- 4 Air is expelled from the intravenous tube in the usual manner.

- 5 The intravenous needle is inserted into the vein, the flow of the plasma being controlled by the screw clamp (S).

For convenient use in emergency, the already assembled apparatus is simply suspended by a wire.

ALTERNATE METHODS

- 1 *Vacuum Method*—1 Screw clamp (S) is tightened (fig. 1)
- 2 Seal A' is punctured and needle B' is forced through diaphragm C'
- 3 Water is allowed to fill the Y of rubber tubing above screw clamp S. Then needle B is forced through diaphragm C. The water will be forced into the plasma bottle by the difference in pressure.
- 4 That part of the Y carrying needle B' is clamped shut near the Y, and diaphragm A is punctured.
- 5 Screw clamp S is loosened and air is expelled from the intravenous tube in the usual manner.
- 6 The intravenous needle is inserted into the vein, the flow of the plasma being controlled by the screw clamp S.

2 *Linear Vacuum Method*—Double ended rubber diaphragm sealed bottles, containing water and plasma, the latter under vacuum are braced in a linear position. A double ended needle is first inserted into the bottle containing water. The other end of this needle is plunged through the top diaphragm of the plasma bottle, and the opposite end of the water bottle is punctured with an open needle containing a filter. The water rapidly enters the plasma bottle. Then a single intravenous tube, fitted at one end with a needle and pinch clamp and carrying on the distal end an intravenous needle, is attached to the bottom end of the bottle containing the prepared plasma solution.

1749 Grand Concourse

SULFAGUANIDINE TOXICITY

SEYMOUR I. COLE, M.D., BROOKLYN

Resident Physician in Medicine, Kings County Hospital

Owing to its efficacy against the bacteria of the intestinal tract and its slow rate of absorption into the blood stream, sulfaguanidine is becoming increasingly widely used as a chemotherapeutic agent for intestinal diseases. The occurrence of severe reactions to sulfaguanidine therapy, however, apparently has not been recorded up to this time.

Although Turell and Leifer¹ have reported a dermatitis appearing during the administration of sulfaguanidine, in their case this may have been due in part to the sulfanilamide, sulfathiazole or sulfapyridine, all of which had been given previously. Ringelman² has reported an eruption associated with sulfaguanidine therapy alone. Marshall and his associates³ observed no toxic effects in a series of 25 children who were given therapeutic doses of sulfaguanidine and only mild reactions in 3 of 25 adults who received the drug. These were in the form of drug fever, unilateral conjunctivitis and a 'possible mild hemolytic anemia.'

Sulfaguanidine is capable of producing more severe reactions. That the clinical use of sulfaguanidine is not without its hazards is shown in the following report.

REPORT OF CASE

A white woman, aged 45, admitted to Kings County Hospital Oct. 27, 1941, had had recurring bouts of diarrhea over the past two years. These various episodes seemed to be precipitated by overwork and nervous strain. At the time of admission she was having six loose movements daily containing blood and mucus.

On proctoscopic examination October 31 the entire rectal mucosa visualized was edematous and friable, bleeding easily. There were flecks of yellowish exudate seen and occasional superficial small ulcerations. A specimen of the exudate was taken for culture. A provisional diagnosis of ulcerative colitis was made. A barium enema showed no obstruction to the passage of opaque material from below. There was a moderate amount of feces and gas present in the large bowel. There was decrease in haustration and slight feathering of the colon outline.

The temperature and the pulse and respiratory rates were within normal limits from the time the patient entered the hospital. Examination of the urine was entirely negative. The patient responded to a high caloric, high vitamin low residue diet and bed rest. Proctoscopic examination November 18, however, revealed that the mucosa of the rectum and sigmoid was still friable and edematous and was covered with a glairy exudate. There were small collections of purulent material.

From the medical services of Drs. Bernhard A. Fedde and Arthur Fankhauser of the Kings County Hospital Open Division.

3 Marshall, E. K., Jr., Bratton, A. C., Edwards, Lydia B., and Walker, Ethel. Sulfaguanidine in the Treatment of Acute Bacillary Dysentery in Children. Bull. Johns Hopkins Hosp. 68: 94 (Jan.), 1941.

which when wiped away revealed several shallow ulcerations. The culture taken on the previous examination yielded growth of *Proteus vulgaris* and a streptococcus. Since the proctoscopic examination still revealed evidence of an ulcerative colitis, sulfaguandine therapy was instituted.

The first dose was calculated at the rate of 0.1 Gm per kilogram of body weight, succeeding doses on the basis of 0.05 Gm per kilogram of body weight were given every four hours.

On the evening of the ninth day of therapy, November 27, after 110 Gm had been given, the patient, who previously had been bearing up well under treatment, complained of severe headache and nausea. Sulfaguandine therapy was withheld at this time. After voiding at 8 p.m., the patient went to sleep and slept soundly.

At 11 o'clock the following morning, the patient complained that she had not voided since the preceding evening and that her headache persisted. Her temperature had risen suddenly from normal to 104 F. Her pulse was 92 a minute and respirations were 24 a minute. There was a diffuse morbilliform eruption over her face, abdomen, chest, back and extremities consisting of small macular areas which varied from 0.5 to 1 cm in diameter. There was very little pruritus and the mucous membranes were not involved.

The urine at this time was amber, specific gravity was 1.022, it was alkaline in reaction and negative for albumin, and sugar was 1 plus. Microscopic examination revealed many sulfaguandine crystals, white blood cells and occasional red blood cells but no casts. The blood sulfaguandine level was 2 mg per hundred cubic centimeters on November 28. Otherwise the blood chemistry was unaltered.

The patient looked extremely toxic. She felt nauseated and at 6 p.m. vomited a moderate amount of watery fluid. A record of the fluid intake and output for November 28 showed an oral intake of 2,600 cc (reinforced by intravenous infusion of 1,000 cc of 10 per cent dextrose in saline solution) with an output of only 130 cc.

The following day, November 29, her pharynx was red and her tongue was coated but moist. She still had the generalized macular erythematous rash, which blanched on pressure. Under the continued regimen of forced fluids, her temperature dropped back to normal and by November 30 the cutaneous rash had practically disappeared. The red and white blood cells and crystals were no longer found in the urine and the patient was voiding adequately. There was no more nausea, vomiting or headache and the patient felt much better.

COMMENT

Sulfanilamide, sulfapyridine, sulfathiazole and, to some extent, sulfadiazine have all been exposed as to their toxic effects. Sulfaguandine may be held under a similar indictment with the other members of the sulfonamide family.

Despite its slow rate of absorption from the gastrointestinal tract, sulfaguandine has produced its harmful side reactions and manifestations of irritation to organs. This seems to be the first noted instance of renal depression and irritation in human beings due to sulfaguandine; it was evidenced by the oliguria and by the presence of red and white blood cells in the urine. (Marshall and others have reported renal depression in experimental animals due to administration of sulfaguandine⁴.)

It is possible that the ulcerated areas of the large bowel permitted more rapid absorption of the sulfaguandine than would occur through the intact bowel wall. This factor should be considered in determining the amount of sulfaguandine to be administered to patients with ulcers in the gastrointestinal mucosa. Since renal complications can occur in a person with normal kidney function, as in this case, it would seem that extra caution should be used if the drug is to be given to a person

with previous renal damage—especially if he has coexisting breaks in his intestinal mucosal surface.

Prompt recovery occurred after the drug was discontinued and fluids were forced to facilitate its excretion. There were no evident after effects.

CONCLUSION

Severe intoxication manifested by nausea, vomiting, headache, sudden temperature rise, morbilliform toxicoderma, oliguria, hematuria and sulfaguandine crystalluria occurred following sulfaguandine therapy. The administration of sulfaguandine is not an entirely innocuous procedure despite its slow rate of absorption from the intestinal wall into the blood stream. Caution should be used in its administration especially if there are factors present which increase the rate of its absorption or decrease the rate of its excretion.

ANGIONEUROTIC EDEMA AND DERMATITIS VENERATA-LIKE LESIONS DUE TO THE ORAL ADMINISTRATION OF SULFATHIAZOLE

CHARLES C. DENNIE, M.D., KANSAS CITY, MO.

Attention has been called to the fact that the sulfonamide group has produced cutaneous and mucous membrane reactions of different varieties. I wish to call attention to two phenomena observed in patients after the administration of small doses of sulfathiazole.

CASE 1—A man aged 42 who was otherwise sound and healthy suffered from pustular lesions on the hands and feet which were due to ringworm fungous infection plus secondary contamination with hemolytic staphylococci.

He was given 12 tablets of sulfathiazole, which he took in three days. A week later he was given another 12 tablets to be taken over Sunday and Monday. He took all but 3 tablets. He then waited two weeks and started to take the remaining 3 tablets of sulfathiazole. About thirty minutes after taking the first of the 3 tablets his tongue began to swell so rapidly that I was forced to go out to his house. The face was swollen, the eyelids closed and both hands and arms showed severe edema. The tongue was so swollen that he could do nothing but mumble. It was impossible to examine his larynx at that time.

He was immediately given 2 mg of epinephrine chloride in oil and taken by car to the hospital. The edema promptly disappeared, and within three days all evidence of the trouble had entirely disappeared, except for a little redness at the edge of his eyelids.

It was considered that this man had become sensitized to the sulfathiazole by taking it during broken periods of time. It is advised that the sulfathiazole be given in these cases but not repeated unless it is absolutely necessary.

Two other cases were encountered.

CASE 2—A man aged 40 who had an infection of the hand was given 3.05 Gm tablets of sulfathiazole. On taking the second tablet he began to itch, and after the third tablet the itching became so severe that I was called to the house to see him.

He had vesicular lesions over both hands and forearms and scattered vesicular lesions over the entire body. The lesions on his hands and forearms resembled *Rhus toxicodendron* poisoning.

He was placed on a milk diet and given baths of aluminum acetate and boric acid followed by the local application of calamine lotion. The eruptions disappeared in about two weeks.

Case 3 was similar in practically all details to case 2.

These 3 cases are reported as unusual toxic manifestations following the oral administration of sulfathiazole. In the 2 latter instances one could well assume that the sulfathiazole or its derivatives were deposited in the skin and produced dermatitis venerata-like eruptions.

HANDBOOK OF NUTRITION II

PROTEINS IN NUTRITION

HOWARD B. LEWIS, PH.D.

ANN ARBOR, MICH.

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition—En

The term protein was suggested by the Dutch chemist Mulder in 1839 as a designation for the universal component of tissues, both plant and animal. Protein was characterized by him as "unquestionably the most important of all known substances in the organic kingdom. Without it no life appears possible on our planet. Through its means the chief phenomena of life are produced."¹ Some sixty years later the primary importance of the proteins was again emphasized by Veiwöndt,² who wrote "The proteins stand at the centre of all organic life." Today, more than a century after Mulder, the proteins are still "first" (Greek, *πρωτεος*) in the regulation of vital processes and disturbances in their metabolism are associated with nutritive failure and with many pathologic conditions with which the physician is confronted.

Proteins are normal constituents of all animal cells and body fluids with the exception of the bile and the urine. They are essential components of both the protoplasm and the nucleus of the cell, hence they exert a profound influence on growth. They are important in the regulation of osmotic relations between cells and intercellular fluids and between tissues and blood and play a significant role in the fluid balance of the body. Many of the best characterized enzymes have been obtained in crystalline form and have the properties of proteins (the "protein enzymes").³ A considerable number of the hormones, chemical regulators of the body, are either proteins (the so-called protein hormones)⁴ or are derivatives of proteins. Many of the substances associated with immunologic and antigenic reactions and similar phenomena are known to be proteins. Finally, in recent years the causative agents of certain virus diseases (notably the tobacco mosaic and the bushy stunt of the tomato) have been obtained in crystalline form and exhibit the characteristic properties of proteins, yet when inoculated into the proper host they multiply and give rise to the specific pathologic changes associated with the virus.⁵ The study of "virus proteins" has become of increasing importance.

It is notable that the proteins exist as large molecules or possibly aggregates of molecules. In table 1 are presented the probable molecular weights of a few

important proteins, as summarized by Svedberg and Pedersen.⁶ The large molecules of even the simpler proteins may be compared with those of some other important constituents of tissues or body fluids: sodium chloride, 58, urea, 60, ascorbic acid, 176, dextrose, 180, lactose, 342, carotene (provitamin A), 537, and glyceryl tristearate (a typical fat), 891.

When this large protein molecule is broken down by the addition of the elements of water (hydrolysis), a considerable number of much simpler units or building stones are formed whose molecular weights range from 75 (aminoacetic acid, known also as glycocoll or glycine) to 240 (cystine). These units have the structure and properties of ampholytes (dissociation so that they may function either as an acid or as a base depending on the pH of the environment) and are known as amino acids. From the chemical standpoint, they are characterized by the presence of a carboxyl ($COOH$) group with acidic properties and an amino (NH_2) group with basic properties, the two groups being attached to the same carbon atom.

The character of the remainder of the amino acid molecule (designated by R, fig. 1) varies, but all the typical products of hydrolysis have in common the presence of the carboxyl and amino groups. Important

TABLE 1—Sources and Probable Molecular Weights of Proteins

Protein	Source	Probable Molecular Weight
Lactalbumin	Milk	1,600
Lactoglobulin	Milk	2,100
Albumin	Egg	2,500
Peptin	Castor oil	3,000
Insulin	Insulin	5,000
Bone tissue protein	Urine	2,000
Ovalbumin	Egg white	2,500
Hemoglobin (man)	100,000	70,000
Serum albumin (horse)	Blood	70,000
Serum globulin (horse-man)	Blood	100,000
Urea	Hemp seed	2,000
Uric acid	Jack bean	4,000
Thyroglobulin	Thyroid	1,000,000
Antipneumococcus serum globulin	Horse blood	1,500,000
Bushy stunt virus	Tomato plant	7,000,000

chemical grouping in various amino acids are sulfur (cystine and methionine), hydroxyl (threonine and serine), benzene nucleus (phenylalanine and tyrosine), guanidine nucleus (arginine), indolyl ring (tryptophan) and imidazolyl ring (histidine).

Certain units or amino acids present in the protein molecule are considered of especial importance in the structure of tissue (growth) and are commonly designated as the essential amino acids. The chemical nature of these essential units will be discussed subsequently. The formulas of the other amino acids may be obtained from any of the numerous standard textbooks on biologic chemistry.

The amino acids are joined to each other in the protein molecule by a linkage known as the peptide linkage, in which the basic (amino) group of one acid is linked to the acidic (carboxyl) group of the adjacent acid with the loss of a molecule of water. A compound made up of two acids thus joined is known as a dipeptide, and a similar compound which contains several (usually an unknown number) amino acids bound together in the peptide linkage is known as a polypeptide.

Hydrolysis of the dipeptide for which the formula is given would break the peptide linkage ($-NH-CO-$), and the component amino acids would be obtained. While the peptide linkage may not be the only linkage

between the amino acids of the protein molecule, it is certainly by far the most important one. This is borne out by the chemical properties of native proteins (proteins as they are found in nature as contrasted with derivatives formed by the action of heat, alcohol, water, salts, enzymes and the like). The biologic reactions of the proteins are also more closely related to those of amino acids than to those of any other type of hydrolytic product of protein, such as proteoses or peptones

An alpha amino acid

Just like the amino acids, which are ampholytes and may react with either acids or bases, depending on the p_H of their environment, the proteins as complexes of amino acids (polypeptides) may combine with either acids or bases. For the most part, the proteins as they exist in fluids and tissues of the animal organism function as acids (play the role of anions) and are in combination with bases (cations). Thus the protein hemoglobin of the erythrocytes is combined in the cell with bases (chiefly potassium) as a salt, similarly milk contains various salts of casein, of which calcium caseinate is important.

When two amino acids are joined in peptide linkage, two different peptides may be obtained, with three amino acids, six peptides, and with five amino acids, 120 peptides. These are known as isomers, since they are all made up of the same units and have the same percentage composition. They differ, however, in the arrangement of the amino acids in the peptide chain (for instance, in the case of a tripeptide, a-b-c, a-c-b, b-a-c, b-c-a, c-a-b and c-b-a, when a, b and c are three different amino acids). Since more than twenty amino acids are known to be of general occurrence in the protein molecule, it is obvious that the possible number of isomeric proteins (polypeptides) is very large. A peptide made up of the twenty amino acids most commonly obtained in the hydrolysis of protein, each acid occurring once only in the chain, would have a molecular weight of 2,499. A simple calculation shows that

Formation of a dipeptide

the number of possible isomers of this peptide would be 2,432,902,008,176,640,000, a number beyond the range of human thought. Each of these peptides would have the same percentage composition, would yield the same amino acids on hydrolysis in the same proportions and would have similar properties. Each would differ from the other in some slight variation in the arrangement of the component amino acids of the peptide chain. Each would therefore be a chemical individual distinct from the other isomeric peptides.

If it is remembered that the protein molecule is much larger than that of the peptide just discussed that native proteins vary greatly in the amounts of amino acids which they yield on hydrolysis and that some linkages other than the simple peptide linkage almost certainly occur in the protein molecule, it is evident that the possible number of different proteins as they exist in nature is almost infinite. This individuality of natural proteins finds expression in the so-called specificity of the proteins. This may be most simply defined by the statement that every species tends to construct within the organism a protein characteristic of that species. Thus, casein of cow's milk is believed to differ from casein of goat's milk, protein of beef muscle to differ from protein of pork muscle and serum protein of human blood to be different from serum protein of beet blood. While in my opinion the basis of this specificity is undoubtedly chemical and is related to the possibilities of isomerism just discussed, this cannot be proved at present. The specificity of proteins of different biologic origin must for the present be demonstrated by biologic reactions, by the reactions observed when "foreign" protein is introduced into the organism. The phenomena of anaphylaxis, of antibody formation, of food allergies and of many other antigenic and immunologic reactions are all manifestations of this biologic specificity of the proteins, so important in many considerations of medical practice.

The protein of the human diet is obtained from both animal and vegetable sources. Among foodstuffs of animal origin, meats (both muscular and glandular tissues), fish, eggs, milk and milk products are most important. Vegetable protein is most readily available in the cereal grains (wheat, corn, rice, rye and barley), the seeds of legumes (peas and various kinds of beans) and many nuts, of which the peanut is perhaps most important in the human diet. It is estimated that the cereals contribute about 25 per cent of the total calories of the diet of the American people.

The proteins of the foodstuffs, large molecules with colloidal properties, do not diffuse readily through biologic membranes. If these dietary proteins are to be utilized, it is necessary that they be altered so that passage through the mucous membrane of the intestine is possible. This is accomplished in the gastrointestinal canal by the process of digestion, by the action of a group of biologic catalysts or enzymes whose activities are so coordinated as to effect a rapid and complete hydrolysis to the soluble diffusible amino acids. Since biologically the amino acids are nonspecific, digestion results in the loss of the biologic specificity of the proteins, if this were not the case, large amounts of "foreign" protein would normally enter the blood stream from the alimentary canal, and food allergies of protein origin would be of very frequent occurrence. In the words of the English physiologist Cathcart: "It is the disintegration of the specific protein to its constituents which are for the most part non-specific which would seem to be the characteristic function of digestion, the breakdown of the colloidal non-dialyzable whole protein to the dialyzable simple peptides and amino acids."

The enzymes concerned in this process are pepsin and rennin of the gastric juice, trypsin and chymotrypsin of the pancreatic juice and a group of enzymes known as peptidases, which are present in the pancreatic and

intestinal juices and hydrolyze the peptides (It should be noted that commercial "trypsin" and the trypsin referred to in the older literature are mixtures of the proteolytic enzymes of pancreatic tissue and include not only trypsin but also chymotrypsin and peptidases⁹ Digestion is best effected if these enzymes act on the proteins of the diet in the natural anatomic sequence, i. e., gastric, pancreatic and intestinal

TABLE 2—*The Amino Acids Essential for Growth of the White Rat*

Amino Acid	Characteristic Chemical Grouping
Threonine	Hydroxy group on 4 carbon chain

Histidine	Imidazole nucleus
Tryptophan	Indole nucleus
Phenylalanine	Benzene nucleus
Methionine	Methyl thiol group
Arginine*	Guanido group

* Arginine has a special position as discussed in the text

Digestion proceeds rapidly in the intestine, the amino acids are absorbed as rapidly as they are formed by the activity of the enzymes. Although digestion studies in vivo with experimental animals with fistulas at various levels throughout the alimentary canal have clearly demonstrated that the major portion of the ingested protein is completely hydrolyzed to amino acids, or at least to very simple peptides,¹⁰ the question of the absorption of some portion of the protein of the diet in unaltered form into the circulation must be considered. Early workers whose experimental methods were not adequate were led to favor the possibility of such an absorption under unusual circumstances, particularly in young animals, in which the intestinal membrane was assumed to be more readily permeable. The use of the newer methods of immunology, by which accurate detection and differentiation of very small amounts of specific proteins have been made possible, has thrown new light on the question. By these methods it now appears to have been demonstrated that in many persons, without regard to age or sex, a detectable amount of certain proteins frequently enters the blood stream in an unaltered state via the alimentary canal. As Walzer¹¹ has expressed it, "The regularity with which the phenomenon occurs in the average individual and the uniformity of results when repeatedly tried under identical conditions on the same subject, preclude the possibility that this is an accidental or unusual occurrence." Of the protein foods studied, the most extensive observations have been reported with egg white.¹² These findings are of special significance in relation to the phenomena of sensitization to specific protein foods. However, it should be remembered that the methods of immunology are capable of detecting exceedingly minute amounts of protein and that the total amount of protein absorbed thus unaltered must be very slight. One may, then, with a reasonable

degree of confidence look to the behavior of the individual amino acids for the interpretation of the role of protein in normal nutrition.

The products of the digestion of proteins, chiefly the amino acids, enter the portal blood on absorption from the intestine and are distributed to the tissues by the systemic blood. The postabsorptive increase in the amino acid nitrogen of the blood, although not large, is unquestioned. The amino acids are rapidly taken up by the tissues, and the amino acid content of the blood returns to normal.¹³

One of three fates awaits the amino acids which thus enter the cell. The first is condensation with other amino acids, selected by the particular tissue in question from the pabulum supplied to it by the blood, to form the protein characteristic of that particular tissue or cell. This specific synthesis, the converse of digestion, makes possible the maintenance of the individuality of the cell. This process requires a particular significance in young animals in which building of new tissues, growth, must occur for normal development and in the adult in normal pregnancy and lactation.

A second metabolic path is utilization of the amino acids for some special purpose in the animal economy apart from the general synthesis of cellular protein. Examples of this are the synthesis of such proteins as hemoglobin, fibrinogen and the serum proteins. Amino acids are utilized also for the formation of specific proteins with hormonal function (insulin and prolactin) or amino acid derivatives which are hormones (epinephrine and thyroxine) or chemical regulators which are not usually classed as hormones (glutathione, histamine and creatine). The synthesis of the "protein enzymes" (pepsin, trypsin, catalase and carbonic anhydrase) also occurs. The details of the reactions which lead to the synthesis of such specialized proteins and protein derivatives are not as yet clearly understood.

After the needs of the cells for these two purposes have been met, an excess of amino acids may still remain in the cells. The fate of this amino acid fraction is deamination—removal of the nitrogenous portion of the molecule—and utilization of the non-nitrogenous portion, since in contrast to fat and carbohydrate storage of protein or amino acids for any considerable time does not appear to be possible. The nitrogenous frac-

tion of the molecule, split off as ammonia, is rapidly converted into urea under normal conditions and is eliminated in this form by the kidneys. The efficiency of this transformation is demonstrated by the fact that normally systemic blood contains less than 0.1 mg of ammonia nitrogen per hundred cubic centimeters, while the urea content of normal blood calculated as urea nitrogen is approximately 17 mg per hundred cubic centimeters. The non-nitrogenous residue which remains

after deamination may either be transformed into dextrose and used in this form, the antiketogenic fraction of the protein molecule, or be converted to fatty acids, the ketogenic fraction of the protein molecule. Whether the non-nitrogenous residue is converted to dextrose for utilization in that form depends on the chemical structure of the original amino acid. In general one may say that about half of the amino acids present in the molecule of any individual protein may give rise to dextrose in intermediary metabolism.

Physiologic and nutritional studies alike have emphasized the role of the amino acids as structural elements, the building stones of living protoplasm. What are the amino acid requirements for the construction of new cells? Are all the amino acids of equal importance in nutrition? These questions have been answered in part by the studies of Rose, which were based on the pioneer work of Hopkins and of Osborne and Mendel. It should be emphasized that the discussion immediately following concerns the requirements for growth of one species, the white rat. Rose¹⁴ first demonstrated that it was possible to obtain normal growth of young white rats when the protein element of the diet was supplied by a mixture of chemically pure amino acids, which included those acids known to be of general occurrence in the protein molecule. The effect of the removal of the various individual amino acids from this mixture was then studied. The absence of certain acids from the diet resulted in impaired growth or in some cases considerable losses in weight and ultimately death. These amino acids, designated as essential, could not be synthesized by the rat and had to be supplied in the diet in adequate amounts or nutritive failure resulted. The withdrawal of other amino acids did not influence the rate of growth. These amino acids, the nonessential amino acids, must therefore be synthesized in the body at a speed commensurate with the needs for normal growth. In tables 2 and 3 are presented Rose's most recent classification¹⁵ of the amino acids on this basis. It has been possible in still further studies to obtain growth in rats fed a mixture of the ten essential amino acids listed in table 2 with the omission of all the acids listed as nonessential. When this essential amino acid mixture was fed at a level of 11.2 per cent of active amino acids normal growth was observed, and at the low level of 5.8 per cent slow growth occurred. In the group of essential amino acids arginine occupies a unique position. Growth is possible in the absence of this amino acid from the diet, but the rate of growth is distinctly less than when arginine is supplied. Rose has defined an indispensable dietary component as "one which cannot be synthesized by the animal organism, out of the materials ordinarily available at a speed commensurate with the demands for normal growth."¹⁶ If this definition is accepted, arginine is classed as essential. This classification of amino acids is one based on the growth requirements of rats. Whether modifications must be made when requirements for pregnancy, lactation or maintenance are under consideration remains to be determined. The possibility of species differences must also be considered. It is known that many of the amino acids are essential for the growth of the young chick. Glycine, however, which can be synthesized by

the rat, appears to be an indispensable amino acid for the chick.¹⁷ The limited data available suggest that from the qualitative standpoint the amino acid requirements of the white rat and of man are similar. Holt and his co-workers have studied the effects of the withdrawal of lysine,¹⁸ tryptophan¹⁹ and arginine²⁰ from the diet of the adult human being. The subjects were fed diets on which maintenance of nitrogenous equilibrium was possible. When either of the first two amino acids was removed from the diet, nitrogen was lost from the body, i. e., negative nitrogen balances were obtained. When the missing amino acids were restored to the diet, nitrogenous equilibrium was again obtained. These observations represent, so far as I know, the first convincing demonstrations of the essential nature of specific amino acids in man. Of particular interest was the finding that when arginine was removed from the diet²⁰ the number of spermatozoa in the seminal plasma was greatly reduced. After the restoration of arginine to the diet, the content of spermatozoa returned to normal. Since the testicular tissue of certain fish is known to be exceedingly high in its content of arginine the authors interpret these findings to indicate that a temporary deficiency of arginine may be met in man by atrophy of the spermatogenic tissue and conclude that arginine also is a human dietary essential. So far as I know, no analyses of the arginine content of human spermatozoa are available. These experiments, which had as one of their objectives "to discover whether deficiencies of particular amino acids produced characteristic pathological changes which could be recognized by clinical or laboratory technics,"¹⁹ are of great importance, and further details should prove of unusual interest.

While experimental evidence is not available in most cases, it seems clear that the rat is able to synthesize the dispensable amino acids if these are not supplied in the diet. The tissue protein synthesized during growth in such experiments must be assumed to be of a type normal and characteristic of the species, since it is considered axiomatic that "the tissues either form a typical protoplasmic product, or none at all."²¹ In the case of the sulfur-containing amino acids, the evidence seems clear that the dispensable cystine may be synthesized from the essential methionine.²²

The function of the essential amino acids, other than for the construction of new protoplasm, is not clear. Studies of the relation of the essential amino acids to the maintenance of adult animals are not extensive. It seems probable, however, that most of the amino acids which are required for growth will be demonstrated to be essential for the maintenance of adult animals. Methionine is a precursor of cystine, an amino acid important in the molecule of the proteins of epidermal structures and also of certain hormones.

particularly insulin, in the molecule of which 12 per cent of cystine is present and no methionine.²³ Methionine also supplies methyl groups for the synthesis of choline, a dietary essential, and of creatine, important for maintenance of muscle function.²⁴ Phenylalanine presumably furnishes the nucleus for the synthesis of thyroxine, the iodine-containing amino acid present in the specialized physiologically active thyroglobulin of the thyroid, and of epinephrine, the endocrine principle of the adrenal medulla. Histidine may be decarboxylated to yield histamine, the amine whose biologic role seems demonstrated.²⁵ Arginine is believed to supply the amidine group for the synthesis of creatine.²⁶ Specific functions for the other essential amino acids are yet to be suggested.

An important application of the observations that properly chosen mixtures of amino acids may replace proteins in nutrition has been the clinical use of protein hydrolysates, prepared for the most part by enzymatic action on proteins *in vitro*. These preparations may be administered either orally or parenterally. The utilization of intravenously injected amino acids over a considerable period was first demonstrated by Henriques and Anderson²⁷ in experiments with a goat. The clinical use of such protein hydrolysates has been studied extensively by Elman²⁸ and others.²⁹ Intravenous administration of protein hydrolysates has been shown to be beneficial when feeding by mouth is not possible or is inadvisable. Since hydrolysis destroys the biologic specificity of the native proteins, protein hydrolysates orally administered have proved of value in supplying nitrogen to persons with severe food allergies.³⁰ Whipple and his co-workers have demonstrated that protein hydrolysates may function effectively in the restoration of plasma protein in dogs whose reserve of tissue and plasma proteins have been depleted by bleeding.³¹ Clinical use of such hydrolysates when plasma is not readily available may become important.

The problem of the amount of protein which is essential or optimal in the diet of man has received much study. Many excellent critical summaries are available.³² Two general methods of approach to this problem have been followed. 1 The endogenous protein metabolism has been determined experimentally, since by many investigators³³ the basal or maintenance requirement for protein is considered to be identical with this fraction. 2 In the statistical approach, the quantity of protein in the diet of well nourished middle class racial groups has been estimated. Since these

diets are usually not on the level of luxury consumption, it is believed that they may afford safe indexes of desirable national nutrition.

It is usually accepted that luxury consumption of protein over prolonged periods is of no permanent value to the adult organism, since in contrast to fat and carbohydrate, protein and its building stones, the amino acids, are not stored. This is seen in the state of nitrogenous equilibrium or balance. If the dietary protein of a normal adult is adequate, the nitrogen of the diet (chiefly protein nitrogen) is equal to the nitrogen of the excreta (mainly the nitrogen of the urine). If to the diet of such a person increased amounts of protein are added, there is a sharp increase in the nitrogenous waste products of the urine (largely urea, derived from protein catabolism), and within a relatively short time nitrogenous equilibrium is again obtained but at a higher level of excretion. If new protein is being synthesized in the body (growth, pregnancy and lactation) the nitrogen excreted is less than that of the diet and the subject is said to be in positive nitrogen balance. When the nitrogen excreted is greater than the dietary nitrogen, a condition of negative balance is obtained. This indicates an inadequate intake of dietary protein or an excessive breakdown of body protein associated with disease.

The level of endogenous nitrogen protein metabolism may be obtained by a consideration of the nitrogen excretion of an adult maintained on a diet high in its content of fat and carbohydrate but containing no protein. Experimentally this has been found to approximate 3 Gm a day for a man weighing 70 Kg, or about 20 Gm of protein.³³ There is however, evidence that to provide a safe allowance for health protein in excess of the requirements for maintenance is essential. It is argued that excessive consumption of protein imposes a burden on the organism and is likely to be harmful. The proponents of the high protein diet, on the other hand argue that a surplus of protein may have a beneficial effect on health and well-being and cite studies of racial groups which indicate that physical efficiency and health can be related directly to the intake of protein and particularly of animal protein. The high protein diet of the Eskimo, in which the protein is obtained almost entirely from meat, does not appear to have resulted in a high incidence of renal disease in this group.³⁴ The careful studies of the metabolism of 2 Arctic explorers who lived for a year in the temperate zone on a diet of meat only are of particular interest.³⁵ It must be remembered, however, that in studies of human populations the protein element is only one of many factors in health and that it is difficult to assess the role of dietary protein alone without many greatly extended studies.³⁶

Outstanding among the pathologic conditions which have been associated with prolonged ingestion of a diet inadequate in its protein content is nutritional edema (known also as war or starvation edema), which has been observed clinically in Europe, in the Orient

and in the United States and can be produced experimentally in animals maintained on a low protein diet³⁷. The continued ingestion of the low protein diet results in low levels of plasma protein (particularly the albumin fraction), and the resultant lowering of the "effective" osmotic pressure of the plasma is believed to be the cause of the edema.

This discussion indicates the desirability of caution in the selection of a standard protein level for national nutrition. Extremes are to be avoided. One of the first attempts to assess the desirable level of protein of the diet by the statistical approach was that of Voit. In a study of the diets of the average laborer in Germany a daily consumption of 118 Gm of protein was observed. So great was the prestige of Voit that this standard allowance of dietary protein was accepted without serious challenge for a quarter of a century. Chittenden of Yale and Hindhede of Copenhagen in the early part of the present century held that the "Voit standard" diet supplied an excessive amount of protein and that a lower level was desirable. It is not necessary to enter into the details of the controversy between the advocates of the low and high protein diet, a controversy which is excellently and impartially presented in the classic text of Graham Lusk³⁸. Sherman, after a careful consideration of the acceptable balance experiments with human beings, in which nitrogen equilibrium was established at low levels of dietary protein, concluded that "a standard allowance of 1 Gm of protein per kilo of body weight per day appears, therefore, to provide a margin of safety of 50 to 100 per cent as far as requirements of adult maintenance are concerned"³⁹. This standard for adult maintenance has been accepted almost universally, while the need for larger amounts of protein in diets of growing children and of pregnant and lactating women is clearly recognized. The recently adopted standards for national nutrition, as proposed by the Food and Nutrition Board of the National Research Council, provide for 70 Gm of protein a day in the diet of a man weighing 70 Kg and 60 Gm of dietary protein for a woman weighing 56 Kg.

Estimates of the increased requirements for protein during pregnancy and lactation vary greatly⁴⁰. The protein requirement per kilogram of body weight is high in infancy and decreases as growth occurs until after puberty, when the adult requirements only are necessary. The desirable amount of dietary protein is estimated to vary from 4 Gm per kilogram a day at 1 to 3 years to 2 Gm at 17 to 18 years. The necessity of protein with high biologic value, such as the proteins of milk, during the period of active growth can hardly be overemphasized. That increased muscular activity necessitates a larger intake of protein is as yet unproved. Traditionally the diet of highly trained athletes and of laborers engaged in hard work, whose caloric requirements are high, contains much meat and supplies large amounts of protein⁴⁰.

The preceding discussion has been concerned with the quantitative aspects of the protein requirements of man. That the dietary protein will be derived from

a wide variety of foodstuffs of both animal and vegetable origin is assumed. In the United States, it is estimated that animal protein makes up at least 50 per cent of the usual diet. If the variety of foodstuffs is limited, care must be exercised in the selection of protein. The chief consideration in the choice of protein must be the furnishing of the essential amino acids to be made available to the tissues by digestion. Since the optimal mixture of the essential amino acids for the nutrition of man is not yet known, the diet must supply all the known essential amino acids in liberal amounts. Animal proteins usually have a greater biologic value than do the proteins of vegetable origin. Thus, *zein*, one of the proteins of the maize kernel, contains no lysine or tryptophan, two important essential amino acids. When the diet is derived exclusively from plant materials, more protein must be eaten. A notable exception is gelatin. This protein, a product of food technology and derived from collagen, completely lacks at least two essential amino acids, valine and tryptophan, and contains little tyrosine and cystine, amino acids which, while not essential may be important in nutrition. Gelatin supplies a mixture of amino acids, which is inadequate if used as the sole or chief source of these tissue-building stones. The recent claims for the superior food value of gelatin require further and more careful study⁴¹. The excellent quality of the mixture of proteins present in milk is notable.

Carbohydrates spare body protein. The breakdown of body protein is significantly increased if the supply of the energy-producing foods and particularly of carbohydrates is not ample. The consideration of the total caloric value of the diet is of special importance when the diet is low in its protein content, as are certain diets prescribed for therapeutic purposes. Diets of high caloric content usually contain liberal or large amounts of protein.

It is known that in the case of certain essential elements present in food (notably the vitamins) the nutritive value may be influenced by preservation processing and cooking⁴². Thus the nutritive values of a natural foodstuff as determined by chemical analysis may not be a safe guide to its value when prepared for consumption. Since foodstuffs which are important sources of protein are seldom consumed in the raw state, possible changes due to heat must be considered. Even milk in present day practice is usually subjected to the mild heat of pasteurization. The evidence in the case of proteins is conflicting. The biologic value of the protein of certain legumes is believed to be increased by cooking while the nutritive value of some other proteins (meat, casein and milk products) appears to be lowered by heat⁴³. A detailed discussion is not possible here. Whether such changes are sufficiently extensive to be of practical significance remains to be determined.

No discussion of recent developments in protein metabolism can neglect the mention of the experiments of Schoenheimer in which isotopic nitrogen (N^{15}) has been used as a marker. These experiments indicate that a "rapid and continuous chemical regeneration of the cell proteins is a general characteristic of living matter," but despite this striking and continuous chemical activity of the organ proteins it is believed that

these processes "lead to no final quantitative or qualitative changes" in the composition of the tissues⁴⁴ This is in confirmation of the older belief in the constancy of composition of the structural elements of protoplasm While the observations of Schoenheimer and his group are of great physiologic significance, it is not believed that at present they suggest any changes in the current practices of dietetics so far as concerns protein

Karl Thomas in 1929 thus summarized the unsolved problems of the biologic value of protein⁴⁵ "What we need to know is 1 Which amino acids must be present in the food, 2 How much we require of each, 3 And to what purpose" Today after more than a decade of intense interest and research in protein metabolism, these questions still epitomize the problem of the role of proteins in nutrition When they can be answered exactly, the role of protein in the diet will be known, and one will be able to determine the dietary value of every mixture of proteins in natural foodstuffs

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

H A CARTER Secretary

"JUNOFORM" TWO-WAY STRETCH ELASTIC HOSIERY ACCEPTABLE

Manufacturer Chesterman-Leeland Company, 406 Memphis Street Philadelphia

Junoform Two Way Stretch Elastic Hosiery is an elastic stocking recommended for varicose veins or other swollen leg conditions The manufacturer states that Junoform Stockings are fashioned through tensions while being knitted which results in a "curving" line following as closely as practical (for reasons of compression) the curving lines of the leg Such design and manufacture are also said to result in a slightly greater supporting pressure around the ankle

An extra end of fine mercerized yarn has been knitted into the stocking in addition to the covered latex yarn resulting in a smooth surfaced stocking This is said to increase the wearing qualities of the stocking as does the fact that the heel is reinforced with nylon twisted with yarn

The following report of a reliable testing laboratory was submitted by the manufacturer as evidence for Junoform Stockings

Heel Joinings 6 221 strokes	Area from Heel to 1 Inch Above Heel 3 768 strokes	Leg Stretch Test Average Six Areas 12 0 pounds
Ankle Stretch Test 15 5 pounds	Single Thickness of Stocking at Calf Area Average 0 0308 inch	Weight of Stockings 1 78 ounces

In the Council's examination of the 'Junoform' stockings, patients who had already been accustomed to wearing latex stockings were provided with the 'Junoform' hose These patients found that the stockings were of uniform tension, that they were of good wearing quality and that they could be washed easily Stockings come in three sizes and can be used for patients who do not require any support above the knee

The Council on Physical Therapy voted to accept the "Junoform" Two-Way Stretch Elastic Hosiery for inclusion on its list of accepted devices

GENERAL ELECTRIC HEAT LAMPS, MODELS IR-4 AND IR-5, ACCEPTABLE

Manufacturer General Electric Company, 1285 Boston Avenue, Bridgeport, Conn

The General Electric Heat Lamps, Models IR-4 and IR 5, are designed to generate infra red radiation Model IR 4 is a table model and IR-5 a floor model Both employ as a source of radiation a bulb on which is inscribed "Reflector Heat—250 Watt, 105-120 volt"

The mounting for the bulb on each of the lamps is of the conventional reflector form, although there is no reflection surface on the mounting the reflector is incorporated in the bulb There is no "Off On" switch in either model

Model IR-5 (the floor model) has a stand adjustable at various heights to 5 feet Adjustments are made by means of screws The base of this unit is rather light and when the stand is at full height it tends to tip easily

Model IR 4 (the table model) has a brackete base with an adjustable bracket Adjustments are made by means of screws

Examination of the lamps showed them to give satisfactory heat radiation for therapeutic use in the home under prescription of a physician

The Council voted to accept the General Electric Heat Lamps Models IR 4 and IR-5 for inclusion in its list of accepted devices

General Electric Heat Lamp Model IR 4

ALOE SHORT WAVE DIATHERMY UNIT ADMIRAL MODEL ACCEPTABLE

Manufacturer A S Aloe Company, 1819 Olive Street St Louis

The Aloe Short Wave Diathermy Unit Admiral Model is designed for use in medical and minor surgical diathermy Mounted in a wooden cabinet the apparatus is equipped with line cord, two rectifier tubes two power tubes two 8 by 10 inch grid electrodes and induction cable The unit operates on alternating current 110 to 125 volts

In the Council's test of the physical characteristics of the instrument the following results were obtained

Electromotive force	115 volts
Power input	940 watts
Power output	300 watts

The final transformer temperature was within the limits prescribed by the Council

The firm submitted evidence to support the ability of the unit to generate heat deep within the tissues In the cuff technique the electrodes were made of a stiff resilient metal so that they embraced the thigh with a springlike action The dimensions were $2\frac{3}{8}$ by 25 inches (upper cuff) and $2\frac{3}{8}$ inches by $18\frac{1}{2}$ inches (lower cuff) The metal strip used in the electrodes was $1\frac{1}{2}$ inches wide The average distance between cuffs was right $7\frac{3}{4}$ inches, left $7\frac{1}{2}$ inches Average spacing was right, 1 inch, left, $\frac{3}{8}$ inch Room temperature was 74°F , humidity was about 42 per cent

Aloe Short Wave Diathermy Unit Commander Model

When the electromagnetic method was tested, the distance between coils was approximately 1 inch About one half inch of spacing was used to separate the coil from the skin The

average thigh circumference was about $19\frac{1}{4}$ inches. The room temperature was approximately 75 F, the humidity was around 48 per cent.

The unit was tried out clinically by a qualified investigator, who reported that it gave satisfaction when used for cuff and coil technic.

Average Temperatures of Six Observations

Cuff Technic			
Deep Muscle		Rectal	
Initial	Final	Initial	Final
97.3	107.3	99.0	99.2
Coil Technic			
Deep Muscle		Rectal	
Initial	Final	Initial	Final
98.7	105.7	99.7	99.8

The Council on Physical Therapy voted to accept the Aloe Short Wave Diathermy Unit, Admiral Model, for inclusion on its list of accepted devices.

MAICO AUDIOMETER, MODEL D-8, ACCEPTABLE

Manufacturer: The Maico Company, Inc., 2632-36 Nicollet Avenue, Minneapolis.

Tests were made on the Maico Audiometer, Model D-8, Serial No. 2987, to determine whether or not the instrument met the requirements of the American Standards Association Proposed Minimum Specifications for Audiometers and for General Diagnostic Purposes Z24.5, as revised Dec. 1, 1937. These specifications coincide with the Council's "Requirements for Consideration of Audiometers" (THE JOURNAL, Feb. 25, 1939, p. 732).

Maico Audiometer Model D-8

A test was made on this audiometer to determine how closely the zero setting of the hearing loss dial agreed with the reference normal threshold which has been established from the work done by the National Health Institute. To obtain the reference normal threshold it was found that the hearing loss dial would have to be set as follows:

Frequency (Cycles per Second)	Setting of Hearing Loss Dial
128	0.2
256	2.8
512	4.8
1,024	3.8
2,048	-1.2
4,096	8.2
8,192	13

It will be noted that the threshold value is within a 5 decibel tolerance except at 4,096 cycles.

The tests were conducted by operating the audiometer from a power source of alternating current of 60 cycles per second at 115 volts.

Numbers refer to paragraphs of the specification.

- 1 Range of frequency of test tone. Complies with specification.
- 2 Control of intensity. Complies with specification.
- 3 Accuracy of frequency. Complies with specification.
- 4 Audiometer calibration. Complies with specification.
- 5 Purity of tone. Complies with specification.
- 6 Extraneous noises. Complies with specification.

The Council on Physical Therapy voted to accept the Maico Audiometer Model D-8, for inclusion on its list of accepted devices.

SODIUM CITRATE (See the Revised Supplement to New and Nonofficial Remedies 1941, p. 26)

The following dosage forms have been accepted:
HOSPITAL LIQUIDS, INC., CHICAGO

Sodium Citrate 2½% W/V in Isotonic Sodium Chloride Solution 35 cc and 70 cc in Filtrair Haemovac containers of 720 cc capacity. A sterile distilled water solution of sodium citrate 2.5 per cent (W/V) and sodium chloride U. S. P. 0.9 per cent (W/V) contained under reduced pressure of not more than 100 mm of mercury in a specially adapted bottle designed for the aspiration, citration and gravity administration of 250 cc or 500 cc of whole blood in indirect transfusion by a closed technic.

U. S. trademark (Haemovac) 379,042

Sodium Citrate 2½% W/V in Isotonic Sodium Chloride Solution 35 cc and 70 cc in Filtrair Sedimentation Haemovac containers of 600 cc capacity. A sterile distilled water solution of sodium citrate 2.5 per cent (W/V) and sodium chloride U. S. P. 0.9 per cent (W/V) contained under reduced pressure of not more than 100 mm of mercury in a specially adapted bottle designed for the aspiration, citration and storage during the sedimentation of 250 cc or 500 cc of whole blood in the preparation of plasma. The container may also be used for the gravity administration of the citrated whole blood in indirect transfusion by a closed technic.

U. S. trademark (Haemovac) 379,042

Sodium Citrate 2½% W/V in Isotonic Sodium Chloride Solution 35 cc in Filtrair Centrifuge Haemovac container of 315 cc capacity. A sterile distilled water solution of sodium citrate 2.5 per cent (W/V) and sodium chloride U. S. P. 0.9 per cent (W/V) contained under reduced pressure of not more than 100 mm of mercury in a specially adapted bottle designed for the aspiration, citration and centrifugation of 250 cc of whole blood in the preparation of blood plasma.

NICOTINIC ACID AMIDE (See New and Nonofficial Remedies, 1941, p. 556)

The following dosage form has been accepted:
GEORGE A. BRON & COMPANY, INC., KANSAS CITY, MO.
Tablets Nicotinic Acid Amide 50 mg

RHUS PREPARATIONS (See New and Nonofficial Remedies 1941, p. 405)

The following preparation has been accepted:
PARKE, DAVIS & COMPANY, DETROIT

Poison Ivy Extract Packages of six 1 cc ampuls

Poison Ivy Extract—A solution in almond oil of a substance extracted from the dried leaves of poison ivy (*Rhus toxicodendron*).

Actions and Uses—Poison ivy extract is used for prevention or treatment of the symptoms of the dermatitis produced through contact with *Rhus toxicodendron*.

Dosage—The prophylactic dose is 1 cc injected intramuscularly for individuals who may habitually come in contact with the plant; the original dose is repeated until three 1 cc injections have been given at weekly intervals. The therapeutic dose is 1 cc given intramuscularly and repeated at twenty-four hour intervals. Two to four doses usually suffice to control the discomfort.

The dried leaves of *Rhus toxicodendron* are extracted with the use of the following procedure: The leaves are dehydrated and decolorized and then concentrated to a solid. The residue is dissolved in sterile distilled water containing 0.5 per cent chlorobutanol as a preservative. A concentrated solution is used to make a 1 per cent extract.

these processes "lead to no final quantitative or qualitative changes" in the composition of the tissues⁴⁴ This is in confirmation of the older belief in the constancy of composition of the structural elements of protoplasm While the observations of Schoenheimer and his group are of great physiologic significance, it is not believed that at present they suggest any changes in the current practices of dietetics so far as concerns protein

Karl Thomas in 1929 thus summarized the unsolved problems of the biologic value of protein⁴⁵ "What we need to know is 1 Which amino acids must be present in the food, 2 How much we require of each, 3 And to what purpose" Today, after more than a decade of intense interest and research in protein metabolism, these questions still epitomize the problem of the role of proteins in nutrition When they can be answered exactly, the role of protein in the diet will be known, and one will be able to determine the dietary value of every mixture of proteins in natural foodstuffs

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS H A CARTER Secretary

"JUNOFORM" TWO-WAY STRETCH ELASTIC HOSIERY ACCEPTABLE

Manufacturer Chesterman-Lecland Company 406 Memphis Street Philadelphia

'Junoform Two Way Stretch Elastic Hosiery is an elastic stocking recommended for varicose veins or other swollen leg conditions The manufacturer states that 'Junoform Stockings are fashioned through tensions while being knitted which results in a 'curving' line, following as closely as practical (for reasons of compression) the curving lines of the leg Such design and manufacture are also said to result in a slightly greater supporting pressure around the ankle

An extra end of fine mercerized yarn has been knitted into the stocking in addition to the covered latex yarn, resulting in a smooth surfaced stocking This is said to increase the wearing qualities of the stocking as does the fact that the heel is reinforced with nylon twisted with yarn

The following report of a reliable testing laboratory was submitted by the manufacturer as evidence for Junoform Stockings

Heel Joinings 6,221 strokes	Area from Heel to 1 Inch Above Heel 3 768 strokes Single Thickness of Stocking at Calf Area Average 0 0308 inch	Leg Stretch Test Average Six Areas 12 0 pounds Weight of Stockings 1 78 ounces
Ankle Stretch Test 15 5 pounds		

In the Council's examination of the "Junoform stockings, patients who had already been accustomed to wearing latex stockings were provided with the "Junoform" hose These patients found that the stockings were of uniform tension, that they were of good wearing quality and that they could be washed easily Stockings come in three sizes and can be used for patients who do not require any support above the knee

The Council on Physical Therapy voted to accept the "Junoform" Two Way Stretch Elastic Hosiery for inclusion on its list of accepted devices

GENERAL ELECTRIC HEAT LAMPS, MODELS IR-4 AND IR-5, ACCEPTABLE

Manufacturer General Electric Company, 1285 Boston Avenue, Bridgeport, Conn

The General Electric Heat Lamps, Models IR-4 and IR 5, are designed to generate infra-red radiation Model IR-4 is a table model and IR-5 a floor model Both employ as a source of radiation a bulb on which is inscribed "Reflector Heat—250 Watt, 105 120 volt"

The mounting for the bulb on each of the lamps is of the conventional reflector form, although there is no reflection surface on the mounting, the reflector is incorporated in the bulb There is no 'Off-On' switch in either model

Model IR 5 (the floor model) has a stand adjustable at various heights to 5 feet Adjustments are made by means of screws The base of this unit is rather light and when the stand is at full height it tends to tip easily

Model IR 4 (the table model) has a bracket base with an adjustable bracket Adjustments are made by means of screws

Examination of the lamps showed them to give satisfactory heat radiation for therapeutic use in the home under prescription of a physician

The Council voted to accept the General Electric Heat Lamps Models IR 4 and IR 5 for inclusion in its list of accepted devices

General Electric Heat Lamp
Model IR-4

ALOE SHORT WAVE DIATHERMY UNIT ADMIRAL MODEL ACCEPTABLE

Manufacturer A S Aloe Company 1819 Olive Street, St Louis

The Aloe Short Wave Diathermy Unit, Admiral Model is designed for use in medical and minor surgical diathermy Mounted in a wooden cabinet the apparatus is equipped with line cord two rectifier tubes two power tubes two 8 by 10 inch pad electrodes and induction cable The unit operates on alternating current 110 to 125 volts

In the Council's test of the physical characteristics of the instrument the following results were obtained

Electromotive force	115 volts
Lower input	940 watts
Power output	300 watts

The final transformer temperature was within the limits prescribed by the Council

The firm submitted evidence to support the ability of the unit to generate heat deep within the tissues In the cuff technique the electrodes were made of a stiff resilient metal so that they embraced the thigh with a springlike action The dimensions were 2 3/8 by 25 inches (upper cuff) and 2 3/8 inches by 18 1/2 inches (lower cuff) The metal strip used in the electrodes was 1 1/2 inches wide The average distance between cuffs was right, 7 3/4 inches, left, 7 1/2 inches Average spacing was right 1 inch, left 7/8 inch Room temperature was 74 F, humidity was about 42 per cent

Aloe Short Wave Diathermy Unit
Commander Model

When the electromagnetic method was tested, the distance between coils was approximately 1 inch About one half inch of spacing was used to separate the coil from the skin The

average thigh circumference was about $19\frac{1}{4}$ inches. The room temperature was approximately 75 F, the humidity was around 48 per cent.

The unit was tried out clinically by a qualified investigator, who reported that it gave satisfaction when used for cuff and coil technic.

Average Temperatures of Six Observations

Cuff Technic			
Deep Muscle		Rectal	
Initial	Final	Initial	Final
97.3	107.3	99.0	99.2
Coil Technic			
Deep Muscle		Rectal	
Initial	Final	Initial	Final
98.7	105.7	99.7	99.8

The Council on Physical Therapy voted to accept the Aloe Short Wave Diathermy Unit, Admiral Model, for inclusion on its list of accepted devices.

MAICO AUDIOMETER, MODEL D-8, ACCEPTABLE

Manufacturer The Maico Company, Inc., 2632-36 Nicollet Avenue, Minneapolis

Tests were made on the Maico Audiometer, Model D-8, Serial No 2987, to determine whether or not the instrument met the requirements of the American Standards Association Proposed Minimum Specifications for Audiometers and for General Diagnostic Purposes Z24.5, as revised Dec 1, 1937. These specifications coincide with the Council's "Requirements for Consideration of Audiometers" (THE JOURNAL, Feb 25, 1939, p 732).

A test was made on this audiometer to determine how closely the zero setting of the hearing loss dial agreed with the reference normal threshold which has been established from the work done by the National Health Institute. To obtain the reference normal threshold it was found that the hearing loss dial would have to be set as follows:

Maico Audiometer Model D-8

Frequency (Cycles per Second)	Setting of Hearing Loss Dial
128	0.2
256	2.8
512	4.8
1024	3.8
2048	-1.2
4096	8.2
8192	1.3

It will be noted that the threshold value is within a 5 decibel tolerance except at 4096 cycles.

The tests were conducted by operating the audiometer from a power source of alternating current of 60 cycles per second at 115 volts.

Numbers refer to paragraphs of the specification.

- 1 Range of frequency of test tone Complies with specification
- 2 Control of intensity Complies with specification
- 3 Accuracy of frequency Complies with specification
- 4 Audiometer calibration Complies with specification
- 5 Purity of tone Complies with specification
- 6 Extraneous noises Complies with specification

The Council on Physical Therapy voted to accept the Maico Audiometer, Model D-8, for inclusion on its list of accepted devices.

SATURDAY, SEPTEMBER 19 1942

TOXICITY OF HUMAN PLASMA

The intradermal test for toxicity of plasma suggested by Levine and State¹ of the University of Minnesota may prove to be a valuable diagnostic aid in clinical medicine and serve as a guide to the preparation of nontoxic commercial products. Contrary to some published views² and to the printed instructions on many lyophilized commercial plasmas, the intravenous administration of human plasma is not "entirely innocuous." Polayes and Squillace,³ for example, recently reported a "near fatal" anaphylactic shock on transfusion of 1 patient with lyophilized plasma, a reaction from which patient recovered only after heroic anti-shock therapy. Subsequent tests revealed an in vitro incompatibility between the lyophilized plasma and the patient's own blood, a prompt agglutination of the patient's erythrocytes taking place, which Polayes assumed to be due to isoagglutinins in the commercial plasma. As a routine precautionary measure he suggested a pretransfusion matching of plasma and the recipient's blood. "In very few cases is the emergency so great as not to afford ample time for such cross matching."

The Minnesota clinicians found that such toxic reactions are much more common than the report of this single case would imply. Of 109 patients tested by them, 20 per cent were demonstrably hypersensitive to one or more of their monovalent samples of plasma. On transfusion the toxic plasma gave distinct nonfatal anaphylactic reactions, the symptoms including headaches, dyspnea, epigastric distress, chills, fever and urticaria.

In order to determine the cause of this toxicity, Levine and State employed numerous technical methods, the most promising being the intradermal injection of

numerous samples of plasma into the prospective recipient. All plasmas used in their dermal tests were siphoned from freshly drawn human blood to which citrate and sulfanilamide had been added as anticoagulant and preservative. The erythrocytes were allowed to sediment for from twenty-four to seventy-two hours at 4 to 8 C before the plasma was removed. During this time autolysis or leukocytic digestion of the erythrocytes presumably took place. The tests were made by the intradermal injection of 0.05 cc of undiluted plasma, and the reactions were read ten, thirty and sixty minutes later. Positive dermal allergy was indicated by the formation of a wheal from 0.8 to 3 cm in diameter plus a surrounding zone of erythema. The erythema alone was without diagnostic significance. The wheal usually appeared in ten minutes, reached a maximum in thirty minutes and began to fade by the end of one hour.

Of 109 patients tested with three or more plasmas, 21 were positive to one or more samples. Sensitivity to a given plasma was not confined to persons of any one blood group. Positive reactions did not occur in all patients to any one plasma sample. Transfer of dermal sensitivity from reacting to nonreacting patients was readily effected.

Nine of the plasma allergic persons were afterward given transfusions with the same plasma. Seven of the 9 exhibited typical nonfatal allergic shock on intravenous administration of this plasma. Other allergic persons were given control injections with dermonegative plasma without producing recognizable posttransfusion symptoms.

The Minnesota clinicians consider three possible explanations for the observed toxicity. First, the reacting plasmas might conceivably contain food proteins or other extraneous allergens, second, they might contain isoagglutinins, or, finally, they might contain free erythrocytic haptens, presumably set free as a result of autolysis. Aubert and his associates⁴ of the S W London Blood Supply Depot have recently reported the presence of both A and B agglutinin in their routine serum and plasma samples. Approximately 50 per cent of all their group A plasmas contained group A haptens. Nearly 85 per cent of their group B plasmas contained group B substance. They found that, if A and B plasmas are pooled in the proportion of 1 part of B to from 2 to 5 parts of A, negligible agglutinin titers result. This is a convenient proportion, since the ratio of A and B donors in the British Isles is approximately 5:1.

Levine and State have confirmed these results and believe that the presence of A and B substances in their plasmas is the principal cause of the positive local allergic toxicity and of the subsequent systemic

¹ Levine Milton and State David. Skin Sensitivity to Human Plasma. *Science* 96: 68 (July 17) 1942.

² Strumia M M, Wagner J A and Moraghan J F. The Intravenous Use of Serum and Plasma Fresh and Preserved. *Ann Surg* 111: 623 (April) 1940.

⁴ Aubert E F, Boorman K E and Dudd B E. The Agglutinin Inhibiting Substance in Human Serum. *J Path & Bact* 54: 89 (Jan) 1942.

anaphylaxis This belief is strengthened by the fact that persons with dermal sensitivity to A or B plasma are also sensitive to Witebsky's corresponding purified A or B substance In their hands, however, pooling of A and B plasmas in a 1:1 ratio failed to neutralize the skin reacting substance Aubert's recommended 5:1 ratio was not tested

Since a negative skin test precludes the possibility of intravenous plasma shock, Levine and State recommend that whenever possible a pretransfusion dermal test should be used for the selection of a nonreacting plasma

THE CHIROPRACTIC THEORY OF PATRIOTISM

The National Serological Society at Davenport, Iowa, has mailed to the chiropractors of the country a letter dated September 3 suggesting that the recipient order so many hundred or so many thousand copies of a four page antivaccinationist pamphlet The letter contains the following irrelevant statements

We have records from the Surgeon General showing that syphilis in compulsory vaccination states is thirty times more prevalent than in states where compulsory vaccination is prohibited by law! Hughes' practice of medicine 14th edition page 184 lists syphilis as one of the complications caused by smallpox vaccination

The secretary of a state board of health writes that the pamphlet is being circulated among superintendents of schools in which that board of health is promoting a campaign for immunization

The letter and the pamphlet indicate that the president of this organization is Cash Asher Asher is the author of a tirade against the editor of THE JOURNAL in particular, and the American Medical Association in general, entitled "Your Life Is In Their Hands" According to the *International Chiropractic News* for July-August 1942 he is also public relations director of the International Chiropractors Association

The pamphlet itself, entitled "Under the Red White and Blue," contains the amazing misinformation that the British government abolished compulsory vaccination and inoculations of all kinds in the army, navy and marine corps in 1939

It quotes the Surgeon General's report for 1919, volume 1, page 38, as giving

the number of admissions to hospitals in 1918 on account of vaccina the disease caused by vaccination, as 10,830 The report for 1918 gives the number of admissions to hospitals during the year 1917 on account of vaccina and typhoid vaccina as 19,608

It then adds

No information is contained in these reports as to the number of deaths resulting from inoculations

The pamphlet discusses with complete disregard for facts or statistical science the rates of smallpox in Italy and Mexico as compared with the United States

After referring to a United Press release dealing with the 28,585 cases of jaundice associated with inoculation against yellow fever, the pamphlet adds

It is doubtful if we would have that many cases of yellow fever if we sent our entire army into the jungles of Africa

Mr Asher has of course no knowledge of yellow fever and probably not enough about jaundice to warrant a comparison

The pamphlet says

An investigation by Congress will reveal that thousands and thousands of American soldiers are collapsing after being inoculated Evidence indicates that between 20 and 40 per cent have to be hospitalized, and that many are incapacitated for service Congress should find out why England abolished compulsory inoculations in the armed forces Who is profiting from the sale of serums to the Army and Navy? We are glad to serve our country, but why maim and immobilize soldiers before they have a chance to serve?

These statements are typical of the lies, false insinuations and similar statements dangerous to Army and public morale promulgated by those who would hinder the war effort

In time of war, epidemics constantly threaten The protection of troops against epidemic disease by routine immunization is accepted as sound practice by the armies of all the warring nations At a time when the health of all the nation, both civilian and armed forces, is essential to eventual victory, such totally unscientific and malicious propaganda continues to arise from sources like Cash Asher And he is public relations director of the International Chiropractors Association!

CHEMISTRY IN RELATION TO THE FOOD INDUSTRY

The program of the one hundred and fourth meeting of the American Chemical Society held in Buffalo, September 7 to 11, emphasized once more the importance of chemistry in the food industries The numerous recent contributions of chemistry in this field have been little short of amazing Many an amateur gardener now routinely dips his cuttings in a solution of indole-acetic acid to accelerate the development of root hairs and thus aid in the establishment of a new plant Treatments with thiamine probably do not do as much for plants as many people hoped they would, but dipping the roots into a solution containing thiamine hydrochloride may help a plant to withstand the shock of transplanting Gardeners and commercial fruit growers alike now spray fruit with chemicals such as thiourea or naphthalene acetic acid to reduce the loss of pears and apples resulting from premature dropping from the trees Presumably these act by some kind of humoral mechanism and cause the fruit to re

on the tree until ripe. In a recent series of tests at the Massachusetts Agricultural Experiment Station the total drop of fruit was reduced from 53 per cent in unsprayed trees to 25 per cent in those that had been treated with naphthalene acetic acid.

Chemistry is continually helping in man's battle against insects. Many kinds of seeds now are disinfected with organic compounds containing either mercury or copper, thus preventing loss through insects or fungus growth. Plant authorities of the Kansas Agricultural Extension Service claim that each dollar invested in seed treatment to control kernel smut of sorghum can be expected to return thirty-five dollars in profit. Treatment of plants to prevent insect damage is essential and new developments are appearing from time to time. Hydrocyanic acid gas is much used to control the confused flour beetle. Pyrethrum is used in many contact sprays, and the suggestion has been made that it be supplemented with a synthetic compound derived from castor oil and known as isobutyl undecylamide or by the more pronounceable name IN-930 of the du Pont Company in order to obtain a more efficient fumigant.

Among the symposiums of the meeting of the American Chemical Society were several especially timely, such as one on methods for the preservation of food-stuffs and their application in the war effort. Papers were presented on the dehydration of meats, fruits and vegetables, on the latest developments of freezing foods and on the cold storage of foods by modern methods. Other papers in this symposium dealt with the nutritional aspects of processing foods and on food requirements for overseas use. The introduction of a new chemical compound on products used by man may also introduce new industrial hazards to workmen and consumers. It is apparent from the nature of the program of the meeting of the American Chemical Society that the physiologic aspects are being given careful consideration.

Current Comment

LIEUT. COL. SAM F. SEELEY DETACHED FROM PROCUREMENT AND ASSIGNMENT SERVICE

Under Medicine and the War in this issue of THE JOURNAL appears an announcement of the detachment of Lieut. Col. Sam F. Seeley from the position of executive officer of the Procurement and Assignment Service and his transfer to active duty with the Army Medical Department. Since its establishment in October 1941 Lieut. Col. Sam F. Seeley has held the position as executive officer of this agency, a position which demanded pioneer work, since a similar agency had not previously existed in our governmental system. In this position he made many friends by his invariable cordiality and geniality. He traveled throughout the country speaking to innumerable organizations of

physicians, dentists and veterinarians and earned for this agency their respect and cooperation. All who were associated with Lieutenant Colonel Seeley in this work wish him the utmost success in the new assignment to which he has been called.

CITRIC ACID IN BONE

A knowledge of the chemistry of tissues aids in the understanding and interpretation of the physiologic reactions and processes in which body substances participate. In certain instances the presence of a chemical compound is established many years before its biologic significance is appreciated. Indeed, information is still lacking concerning the part played by some body components in metabolic transformations. One of the latter group of substances is citric acid, whose presence in the animal organism has been known since 1888, when it was first isolated from cow's milk. Some forty years later citric acid was isolated from normal human urine, and this organic acid has since been shown to occur in relatively low concentrations in various tissues of the body. The concentration of citric acid in soft tissues has been reported as falling in the range of 0.1 to 2.0 mg. per hundred grams of tissue, whereas the acid is present in considerably greater amounts in body fluids (20 to 200 mg. per hundred cubic centimeters of fluid).¹ Recently, Dickens,² in the course of an investigation of the citric acid content of tumor tissue, found that the hard substance of bone constitutes a heretofore unsuspected store of citric acid which may amount to some 70 per cent of that contained in the whole body. On a dry fat and protein free basis bone was shown to contain over 1 per cent of citric acid. The analytic data were confirmed by actual isolation in 80 per cent of the yield calculated from analysis. Variations in the citrate content of bone probably due to endocrine and dietary factors, were also reported. The variations in citric acid content of bone greatly exceeded those of the other bone constituents, suggesting that the citrate is in a readily available form *in vivo*. However, *in vitro* the organic acid could not be readily extracted from dried powdered bone by water, alcohol or ether. The fact that so large a quantity of a familiar substance has heretofore escaped detection by bone analysis is surprising, but most accurate and complete analyses have been made on bone ash, thus the citrate would presumably appear in the carbonate fraction. The nature of the organic combination of bone cations has long been an almost uninvestigated field and a systematic study of bone for the presence of other physiologically important organic acids would now appear indicated. It may be tentatively assumed that the citrate may be present in simple or complex combination with calcium, although the nature of the distribution of citric acid in bone, and its possible roles in structural and metabolic functions in this tissue, are important problems for future investigations.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

DR SEELEY TRANSFERRED FROM PROCUREMENT AND ASSIGNMENT SERVICE

The Directing Board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians has formally expressed its appreciation of the services rendered by Col Sam F Seeley, who has been transferred to military duty. Following is the text of the resolution adopted:

The transfer of Lieut Col Sam F Seeley from his connection with the Procurement and Assignment Service to active military duty causes a great loss. Colonel Seeley, who has acted as executive officer since the beginning of this service, has been transferred to military duty, which is in keeping with the policy recently adopted by the War Department. His training and experience with the Medical Corps of the Army in his professional capacity amply justifies such a step.

The Directing Board of the Procurement and Assignment Service wishes to take this opportunity of expressing to the Surgeon General of the United States Army its very deep appreciation for the valuable service which Colonel Seeley has rendered during its period of organization and functions.

The Directing Board expresses to Colonel Seeley its deep appreciation for the great sacrifice which he has made in dislocating himself from actual military duty to serve with us in an executive capacity. He has been most unselfish and has given unstintingly of his time, energy and patience in helping to solve many of the problems connected with the functioning of the Procurement and Assignment Service. He has not only labored faithfully at our office in Washington but he has traveled over the United States contacting many of his professional confreres and explaining to them the purpose for which the Procurement and Assignment Service was organized. His services have been most valuable and have helped to take us a long way in accomplishing the objectives for which it was created.

The Directing Board expresses to Colonel Seeley its gratitude and thanks for his unselfish devotion to the organization of the Procurement and Assignment Service and wishes for him the greatest success in his new assignment.

PHYSICIANS FOR EMERGENCY BASE HOSPITALS

Units of physicians are being organized to help care for casualties and other patients who may be moved, in case of enemy attack, from hospitals in exposed cities to emergency base hospitals in the interior. James M Landis, director of the Office of Civilian Defense, announced on September 7. The units are being established in selected medical schools and hospitals in the coastal states. Invitations to form such units as part of the joint program of the Medical Division of the Office of Civilian Defense and the Public Health Service for war-time protection of the civilian population were issued by the Surgeon General of the U S Public Health Service (see THE JOURNAL, September 5, p 57).

The new affiliated units of physicians will be assigned to emergency base hospitals whenever it becomes necessary to supplement the existing staff. Each group will operate as a unit. It will be composed of fifteen physicians and will include specialists in internal medicine, general surgeons, orthopedic surgeons, a dental surgeon, a pathologist and a radiologist.

All the physicians will receive commissions in the U S Public Health Service Reserve but will be called to active duty only if hospital patients in their own regions must be removed to emergency base hospitals or if the civilian population is moved because of enemy action. Unless such an urgent need arises, the physicians will remain on an inactive status for the duration of the war.

EQUIPMENT FOR EMERGENCY MEDICAL SERVICES

The chairman of the State Health Preparedness Commission, Assemblyman Lee B Mailler, said in a recent report that one of the most serious problems of the commission at present is equipment. The commission has encouraged communities to obtain a minimum amount, at least, of emergency medical field unit equipment from their own resources. Many communities which have done this have available blankets, cots, stretchers and first aid kits. The commission was able to secure federal approval for allocating funds to nine hospitals in strategic New York areas and nine in New York City to assist in the development of blood plasma banks. These hospitals agreed to build up a reserve blood plasma equaling 1 unit (equivalent to 1 pint of whole blood) for each hospital bed, which reserve is to be used for civilian casualties. For example, the Strong Memorial Hospital in Rochester, N Y, received a federal grant of \$2000 and has already in operation an ideal plant for rapid production of dried plasma, and the Rochester Red Cross with the assistance of the hospital, has been securing donors at the rate of 4,000 a month. The Red Cross will hold in reserve, chairman Mailler said, for civilian use a large supply of frozen blood plasma which will be made available to any communities needing it in case of emergency. Efforts are being made also to establish a mobile plasma unit and processing plant at the state laboratory in Albany, which would visit the smaller communities of the state to collect blood and thus form a reserve of plasma available especially for these communities.

AMERICAN FLYING SERVICES FOUNDATION

The object of the medical division of this organization is to repair the physical defects of young men who desire to serve in the flying forces of the United States. When physical defects bar them from becoming military aviators they may be referred provided they have the make-up that qualifies them as aviators to the American Flying Services Foundation which places them in the hands of qualified physicians for medical or surgical treatment, including dentistry and hospitalization, in order to make them available as cadets for the flying services. The flight surgeons of the Army and Navy who examine these boys unofficially refer them to the foundation, which through its regional medical committees arranges and finances such medical treatment and hospitalization as may be necessary for the foregoing purpose. The foundation pays the hospital, the doctor and the dentist for such work as may be done, bearing in mind first of all the use of the applicant's own family physician or dentist whenever possible and desired by the applicant. The medical division of the foundation looks at each individual's problem from the flight surgeon's point of view and does only those things that it is asked to do. According to Dr Samuel M Strong, medical director of the foundation, this is purely a voluntary organization in which the heads of the departments receive absolutely no remuneration directly or indirectly. The

American Flying Services Foundation, which was founded by World War I fliers for the fliers of today, has an advisory board and a board of trustees a medical council and regional medical committees. The medical headquarters are at 140 East Fifty-Fourth Street New York. The report of the medical division for the week ended August 15, for example, shows that the foundation received applications from young men in nineteen states.

MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

This committee, with headquarters at 420 Lexington Avenue, New York City has in the last two years furnished supplies valued at \$466,815.95 to needy hospitals, evacuation centers and welfare organizations in the United States, Alaska and Hawaii, to Russian relief groups to the British Red Cross to the American Friends Ambulance Unit in China and to the Free French. At the annual meeting of the executive board of the committee in New York on August 19 Dr Joseph P. Hognet, national medical director, said that the greatest demand had been for medical and surgical instruments, antitoxins, vitamin concentrates and the sulfonamide drugs. In view of the increasing number of the physicians who serve on this committee who have gone into the military service plans are being made to form a group of nonprofessional men and women to supplement the work of physicians affiliated with the committee. Efforts also are being made to increase the present professional membership of the committee from 415 to 600 by the end of the coming fiscal year. In a news release the committee acknowledged contributions of drugs and instruments from numerous organizations throughout the country including medical societies, hospitals, women's auxiliaries, clinics, pharmaceutical houses and other manufacturing companies.

FIGHTERS IN WHITE A MOVIE

The New York State Department of Health in cooperation with the New York State Health Preparedness Commission has produced for the State War Council a sound motion picture entitled 'Fighters in White,' which shows the operation of the emergency medical services established in the state of New York in accordance with procedures outlined by the United States Office of Civilian Defense. To the first preview given in Albany, August 25, were invited the governor, the State War Council, the heads of state departments, the mayor and other officials. A second preview was given in New York City the following day, to which Mayor LaGuardia, Dr Ernest L. Stebbins, commissioner of health of the city, and others were invited. The scenario was written by the research editor of the Health Preparedness Commission, Benjamin Martin, and the technical adviser was Dr John J. Bourke, research director of the Health Preparedness Commission.

PARACHUTES TO DROP DOCTORS AND NURSES

Regional Director J. M. Loughlin of the first civilian defense area recently announced the formation of a parachute corps to drop doctors and nurses to stricken areas in out of the way places. The corps was organized by the Civil Air Patrol in New England under the direction of Major R. S. Fogg, regional commander of the Civil Air Patrol, on the rolls of which already are twenty-five doctors and thirty nurses, some of whom own their own airplanes according to the Boston *Globe*.

FLORISTS FORM AMBULANCE CORPS

The Philadelphia Council of Defense announced on July 11, according to the Philadelphia *Record* that the florists of the city had formed an emergency ambulance corps, utilizing their trucks as ambulances and equipping them with stretchers and first aid equipment and having their drivers instructed in first aid under the supervision of Dr A. P. Keegan, chief of the Medical Corps of Defense Council of Philadelphia.

UNITED CHINA RELIEF

The president of the United China Relief, Paul G. Hoffman, is reported to have said on August 4 that funds sent by this organization to China in the first six months of 1942 amounted to \$1,861,261, which provided for the manufacture of 4120,000 doses of cholera and typhoid vaccine, provided medical care for wounded soldiers, aided in expanding the emergency medical service training school and helped expand China's industries. The report, made public by United China Relief headquarters in New York, further revealed that relief had been provided for 361,445 refugees from Hong Kong, Burma and the East Indies, that aid had been sent to 21,000 orphan children and that four Christian colleges had been reestablished in the interior of China. Mr. Hoffman stated that the disbursements in China of United China Relief are handled chiefly through the National Red Cross Society of China, the Chinese Y. M. C. A., Protestant and Catholic missions and other institutions. The workers, except for a few full time administrators, serve without pay.

RURAL DRESSING STATIONS IN DELAWARE

More than a hundred and seventy-five dressing stations were being established in private dwellings and garages throughout Newcastle County in Delaware according to the *Wilmington Journal* of July 11, so that in case of air raids in this rural area, civilian injuries might be treated immediately. A typical dressing station in this group is said to comprise three cots and room for many more, and a staff of two trained nurses and thirteen other women. The more serious injuries would be treated at the twenty-two casualty stations in Newcastle County, which are located in schools, firehouses and other public buildings and those requiring still further medical care will be moved from these stations to hospitals in Wilmington.

COURSE IN CHEMICAL WARFARE

A course sponsored by the Office of Civilian Defense, the Johns Hopkins University and the Chemical Warfare School had up to July 12 been attended by some forty-five doctors from six states, seventeen of whom from Baltimore and vicinity completed the course on July 11. The instruction, which takes in protection against war gases and treatment of chemical casualties, also will be given to laymen.

PHYSICIANS WILLING TO GO INTO INDUSTRIAL MEDICINE

In the office of the state medical chairman for the Procurement and Assignment Service there are lists of physicians who have indicated their willingness or desire to go into industrial medicine. The names of these physicians may be secured by writing to the state medical chairman in the state in which the industry is located.

THEOBROMINE AND CAFFEINE

Recently the War Production Board issued Conservation Order M-222 to control the use of theobromine and caffeine. For the purposes of the order, theobromine means 3,7-dimethylxanthine, whether synthetic or natural in crude or refined form, and the term shall include any compound of theobromine but shall not include standard dosage forms (tablets, capsules, ampules, solutions and so on). Caffeine means 1,3,7-trimethylxanthine and is subject to the same general definition as theobromine.

On and after Oct. 1, 1942 no producer shall use any theobromine or caffeine other than stocks in his hands on said date no producer or distributor shall deliver any theobromine or caffeine, and no person (other than a wholesaler or retailer) shall accept delivery of any theobromine or caffeine except as specifically authorized by the Director General for Operations on application, or except under the exemption provided, which states that 'this order shall not be required with respect to the delivery to any person or the acceptance of delivery or use by any person of 2 pounds or less of theobromine and 2 pounds

or less of caffeine during any one calendar month. Such use or delivery may be made without regard to preference ratings.

Each person seeking authorization by the Director General for Operations to accept delivery of and use theobromine or caffeine during any calendar month shall place his purchase order with his supplier on or before the 12th day of the month preceding the month for which authorization to accept delivery is requested and shall file two copies of Form PD-600 with the War Production Board on or before such date. He shall also send one copy of such form to his supplier along with his purchase order. Copies of Form PD-600 may be obtained at the local offices of the War Production Board. Any producer seeking authorization to use theobromine or caffeine during any calendar month shall file two copies of Form PD-600 with the War Production Board on or before such date. Each producer and each distributor seeking authorization to make deliveries of theobromine or caffeine shall file with the War Production Board on or before Sept. 20, 1942 and on or before the 20th day of each month thereafter three copies of Form PD 601.

Unless otherwise authorized or directed by the Director General for Operations, no producer shall hereafter methylate theobromine to caffeine except to fill purchase orders for caffeine which he has been specifically authorized to fill and/or to maintain a practicable minimum working inventory of caffeine. No producer shall, during any calendar month methylate any theobromine to caffeine unless and until provision has been made by such producer to make all deliveries of theobromine which have been directed by the Director General for Operations to be made by him during such month.

The prohibitions and restrictions of this order shall apply not only to deliveries to other persons including affiliates and subsidiaries, but also to deliveries from one branch, division or section of a single enterprise to another branch, division or section of the same or any other enterprise under common ownership or control.

Producers and distributors are to notify their regular customers of this order as soon as possible, but failure to give such notice does not excuse any one from the obligation of complying with its terms. All reports, applications and communications should be addressed, unless otherwise directed, to War Production Board, Health Supplies Branch, Washington, D. C., Ref. M-222.

AVIATION MEDICAL EXAMINERS

A routine course of instruction to qualify army medical officers for duty as aviation medical examiners recently began at the School of Aviation Medicine, Randolph Field, Texas. The following officers were enrolled:

ALABAMA		Homer L. Comparette	Captain
George K. Spearman	1st Lieut., Anniston	Washington	
ARIZONA		Edwin E. Corcoran	Captain Wash
Angus J. Fillmore	Captain Mesa	Frank E. Gibson, Jr.	Captain Washington
ARKANSAS		Samuel C. Harwood	Captain Washington
Neil H. Sullenberger	1st Lieut., Camden	Richard L. Jackson	1st Lieut. Washington
CALIFORNIA		Edward A. Kelly	Captain Wash
Lester F. Allison	Captain Fresno	Austin Lowrey, Jr.	Major Wash
Lyman H. Conner	1st Lieut. Burbank	GEORGIA	
Albert E. Fleming	1st Lieut., Fresno	Adolph S. Sanchez	Captain Exton
Andrew B. Goddard	1st Lieut. Mill Valley	ILLINOIS	
Edward Luston	Captain Palo Alto	Edward G. Cada	Captain Berwyn
Harvey C. Maxwell	Major Santa Ana	William W. Curtis	1st Lieut. Chicago
Robert I. Merrill	1st Lieut. Hemet	Louis S. Frank	1st Lieut. Chicago
Frank A. Moran	Captain San Francisco	Dominic J. Haftkowski	1st Lieut. Chicago
Lionel Oyey	1st Lieut. Los Angeles	Edgar O. Hughes	1st Lieut. Washington
Montmore C. Shwayder	1st Lieut. San Francisco	Walter S. Miller	Captain Rock
DISTRICT OF COLUMBIA		Theodore C. Papermaster	1st Lieut. Chicago
George L. Ball	Major Washington	Jack L. Restivo	1st Lieut. Chicago
William E. Barry	Major Wash	INDIANA	
ington		Eugene W. Austin	1st Lieut. Anderson

Archie E. Brown 1st Lieut. Indianapolis
William B. Chaffman 1st Lieut. Mount Vernon
Kenneth E. Comer 1st Lieut. Mooresville
James H. Gosman 1st Lieut. Jasper

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Bill Introduced—H R 7534, introduced by Representative Eliot, Massachusetts, proposes to amend and extend the provisions of the Social Security Act. Among other changes, this sixty-eight page bill provides for systems (1) of disability insurance benefits, including medical, surgical, institutional, rehabilitation and other services to be supplied by the Social Security Board, (2) of temporary disability or sickness benefits, (3) of maternity benefits conditioned on compliance with such regulations with respect to antepartum, confinement and postpartum care as may be prescribed by the board, and (4) of hospitalization benefits of not less than \$3 nor more than \$6 for each day

of hospitalization, such benefits to be available to the wife and children of the employee. In lieu of the payment of such benefits to beneficiaries, the bill proposes, the board may make arrangements with accredited hospitals for the payment of the reasonable cost of hospital services. The base of the act will be broadened to embrace within the Old Age and Survivors' Insurance provisions certain employment now exempt, such as employment in connection with charitable, scientific and educational institutions, and what the bill renames as "social insurance contributions" by employers and employees will be increased to 5 per cent for the calendar years 1943, 1944 and 1945, to 5.5 per cent for the calendar years 1946, 1947 and 1948, and to 6 per cent for each calendar year thereafter.

WOMAN'S AUXILIARY

Minnesota

Mrs E M Baldigo, Red Wing, Minn., opened her home to the Goodhue County medical auxiliary recently. Mrs E H Juers presented material on the use of puppet shows in teaching school children the reasons for vaccination and inoculations.

A successful Red Cross benefit party in the form of a show entitled 'The Gay Nineties' was given recently by the Hennepin County auxiliary, Minneapolis.

Pennsylvania

At the April meeting of the Cambria auxiliary, Mrs Esther Strong Karakashian, the guest speaker, gave an account of life in Palestine.

At the meeting of the Dauphin auxiliary recently at the Harrisburg Academy of Medicine, Mrs W M Gilbert, the guest speaker, spoke on "Nutrition for Defense." At the annual public relations meeting, April 7, at the academy, health programs for young people was the subject of a forum conducted by local leaders of youth groups. The speakers were Mrs Henry W Taylor, executive secretary of the Tuberculosis and Health Society of Harrisburg, Dr Eleanor R Stein, on school health programs, Miss Marian McGimsey, physical education instructor at Seiler School, Miss Edith L Groner, executive secretary of the Y W C A, and Miss Catherine Steltz, director of the Harrisburg Area of Girl Scouts.

At the twelfth annual health institute held at the County Medical Society Building, Philadelphia, about sixty organizations were represented. The speakers and their subjects were as follows: Drs Louis H Clerf, "Greeting", Katharine O Elsom, "Vitamins in Relation to National Defense", John H Gunter, "Nutrition and the Teeth", Earl D Bond, "Nutrition and the Emotions", Mrs Charles C Course, "Responsibility of the Doctor's Wife in This Crisis", Stanley P Remann, "Cancer as It Concerns You", Lieut Col Arthur P Hitchens, "Nutrition, Health and Defense", and Lewis T Buckman, president of the Medical Society of the State of Pennsylvania, "Organized Efforts in Medical Defense."

The Crawford County auxiliary was addressed recently by Mrs Amy Driver Heath, nutritionist in Meadville on 'Feeding Efficiency', Dr Herman H Walker, councilor for the eighth district, talked about the blood bank established by the Crawford County Medical Society.

Texas

The twenty-fourth annual session of the Woman's Auxiliary to the State Medical Association of Texas was held in Houston, May 11-14, with a registration of 309. During the entire meet-

ing open house was held in a reception suite at the Lamar Hotel, with members of the Harris County auxiliary as hostesses. Mrs Frank J Liams Houston, was in charge of the reception suite. The entertainment included the reading of the "White Cliffs of Dover" by Mrs T E Kummerley of Houston.

May 12 a breakfast for council women and district presidents was held at the Rice Hotel. In the afternoon about 300 members and visitors of the auxiliary attended the tea held at the Houston Country Club, honoring Mrs S F Harrington of Dallas, Mrs P R Denman of Houston and Mrs J U Reaves of Mobile Ala. Mrs J H Wooters was the local chairman of arrangements. A ball honoring Dr N D Buie, Marlin, president of the state medical association, was held in the Grand Ballroom. The Past Presidents Dinner was held in the home of Dr and Mrs M L Graves, eleven past presidents were present.

May 13 the second general business meeting of the auxiliary was held at the Lamar Hotel, with Mrs Harrington, president, presiding. Dr Buie brought greetings. At this time all reports of the council women and county auxiliary presidents were heard. At noon the business session adjourned to the San Jacinto Inn for a "no-host" luncheon, at which Mrs Ramsay H Moore installed the new officers. Mrs Reaves, president of the auxiliary to the Southern Medical Society, gave an inspiring address.

May 14 Mrs Denman entertained the members of the Executive Board with a breakfast, at which plans for the year were made.

Bexar County auxiliary is sponsoring a party each month for service men. Mrs John Pridgeon, president, has been appointed chairman of the medical division to canvass the city of San Antonio to obtain medical supplies and equipment for emergency civilian defense. The auxiliary voted to equip ward 5 at the Ellington Field Hospital with books, games and music to make the soldiers' convalescence more pleasant.

Virginia

The Petersburg auxiliary has devoted its efforts for two years to securing funds to meet its pledge of \$900 to the new Petersburg Hospital. A check for \$350 was forwarded to the hospital in January making the total \$550 which the auxiliary to date has contributed to the new building. For the past several years the linen supply of the Petersburg Hospital has been supplied by a shower sponsored by the auxiliary. A shower was given recently at the Nurses Home. The estimated value of the linen received was \$315.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARIZONA

Personal—Dr Seth F H Howes, assistant superintendent of the New Hampshire State Hospital at Concord, was appointed superintendent of the Arizona State Hospital, Phoenix, July 11. The position has been open since Dr Otto L Bendheim was given a leave of absence to enter military service.—Dr Grover C Daniel, manager of the Veterans Administration Facility in Walla Walla Wash, since 1939, has been named to a similar position at the facility in Whipple to succeed Dr Walter B Swackhamer, retired.

Program of Health Education—The Maricopa County Health Department is cooperating in a program of health education in Phoenix and Maricopa County, which will consist of three projects: a teacher training program in health education to be conducted in cooperation with school authorities in Phoenix and the county and the Arizona State Teachers College at Tempe, an adult health education program for community groups in both urban and rural areas of the county to consist of radio and newspaper publicity, lectures and motion pictures under the supervision of the director of the Maricopa County Health Department and an educational program for food handlers to be conducted in cooperation with the division of sanitary engineering of the state department of health to be one of a series of such programs planned for each area of the state.

CONNECTICUT

Dr Kuh Goes to California—Dr Clifford Kuh, New Haven, for a number of years chairman of the committee on industrial health of the Connecticut State Medical Society, has resigned to become director of the bureau of industrial health for the California State Department of Health.

Annual Clinical Congress—The Connecticut State Medical Society will hold its clinical congress at the Sterling Law Buildings, Yale University, New Haven, September 29-October 1. The program includes the following speakers:

Dr William W Herrick New York Medical Aspects of Obstetrics
Dr William E Studdiford Jr New York Clinical Significance of Bleeding During First Half of Pregnancy
Dr Benjamin P Watson New York Clinical Significance of Bleeding During Second Half of Pregnancy
Dr George G Ward New York The Intelligent Gynecological Examination
Dr Mortimer D Speiser New York Lesions of the Female External Genital Tract Susceptible to Office Treatment
Dr Ephraim Shorr New York Clinical Experiences with Synthetic Estrogens
Dr Julian B Herrmann New York Aspiration Biopsy a Technique for Cancer Diagnosis
Dr Philip Levine Newark N J The Rh Factor in Erythroblastosis
Dr Louis K Diamond Boston Anemias of Childhood and Their Therapy
Dr James M Cunningham Hartford The Antisocial Child
Dr Robert Elman St Louis Recent Advances in Surgery from the Standpoint of Improving Prognosis
Dr Reginald H Smithwick Boston Differential Diagnosis and Treatment of Peripheral Vascular Disease of the Extremities
Dr Philip D Wilson New York War Injuries and Their Treatment
Dr Frank R Ober Boston Poliomyelitis and the Kenny Treatment
Dr John R Cobb New York Treatment of Scoliosis
Dr Dudley J Morton New York Foot Disabilities
Dr William T Green Boston Pediatric Orthopedic Problems
Dr John M Kenney New York Use of Radioactive Phosphorus in Malignant Diseases
Dr Charles B Huggins Chicago Castration in Prostatic Neoplasms
Dr Joseph Weiner New Haven, Treatment of Acute Attack of Asthma
Dr Harry Eagle Baltimore U S Public Health Service The Intensive Treatment of Early Syphilis in Two or Three Months by Triweekly Injections of Mapharsen
Dr Robert Gordon Douglas New York Chemotherapy of the Urinary Tract
Dr Lester M Morrison Philadelphia Chemotherapy of the Gastrointestinal Tract
Dr Maxwell Finland Boston Chemotherapy in the Bacteremias
Dr Champ Lyons Boston Chemotherapy in Otolaryngology
Dr Phillips Thigerson New York Chemotherapy in Disease of the Eye
Dr Bertram Shaffer Philadelphia Chemotherapy in Dermatology
Dr Henry E Meloney New York Modern Treatment of Malaria
Dr Francis G Blake New Haven Use of Penicillin

Capt James E Crane, M C, U S Army, formerly of Standard will address the luncheon Tuesday on 'Experiences of a Flight Surgeon in the South Pacific'. There will be a question and answer session conducted on Wednesday by Dr Clay Ray Murray New York, and one on Thursday conducted by Drs Finland Lyons Douglas, Morrison and Blake.

DISTRICT OF COLUMBIA

Stockingless Women Prohibited from Trying on New Shoes—Dr George C Ruhland, health officer of the district recently issued a letter to local shoe dealers requesting their cooperation in preventing stockingless women from trying on shoes in order to discourage spread of "athlete's foot," it is reported.

Course in Tropical Medicine—Ernest Carroll Faust, Ph D, head of the division of tropical medicine, Tulane University of Louisiana School of Medicine New Orleans recently conducted a short course in tropical medicine at the U S Army Medical School. Dr Faust has been consultant in tropical medicine at the army medical school since 1941.

Hospital Asks Patients to Forego Luxury—A pamphlet issued by Doctors Hospital contains an appeal to patients not to expect luxuries which they received in the hospital before the war. The brochure points out that hospitals are not an exception to the drain on manpower imposed by the war and recommends, among other things the discontinuance of morning visiting hours and 'alcohol rubs to convalescing patients who are not confined to bed'.

Annual Scientific Assembly—The Medical Society of the District of Columbia will hold its fourteenth annual scientific assembly at the Mayflower Hotel September 29-October 1. The theme of the meeting this year will be 'Medical Problems of the War Era' with sessions being divided into discussion on "Diagnosis and Treatment of Infectious Diseases" and "Treatment of War Injuries". Included among the speakers will be:

Dr Joseph Stokes Jr Philadelphia Epidemic Influenza
Dr Colin M MacLeod, New York Present Status of the Pneumonia Problem
Dr John H Dingle Boston Certain Aspects of the Treatment of Meningitis
Lieut. Comdr LeRoy D Fothergill M C U S Navy Reserve Scarlet Fever The Unitarian Concept of Streptococcal Disease
Dr Richard P Strong Boston Acute Diarrheal Diseases Other Than Amebic Dysentery
Dr Warfield M Tyror Baltimore Intestinal Antisepsis with Special Reference to Succinylsulfathiazole
Admiral Sir Andrew B Cunningham head of the British Admiralty Delegation in Washington War Conditions in the Royal Navy
Commander James R Fulton M C U S Navy Bethesda Md Sulfonamides in the Emergency Treatment of Wound
Colonel Frank S Gillespie British Army Medical Service British Medical and Surgical Experiences in the Middle East

There will be a panel discussion on the sulfonamides Wednesday afternoon by Drs Harrison F Flippin (Philadelphia), Harry F Dowling Sanford M Rosenthal, James Ross Veil and William Calhoun Stirling.

ILLINOIS

Division of Child Welfare Reorganized—A new administrative setup has been announced for the state division of child welfare under a program of reorganization which is under way. The change includes the creation of five regional offices to direct and supervise all division services under a regional supervisor. The regional supervisors will be responsible administratively and functionally to the supervisor of case work services, who will direct and supervise all field operations. Additional changes have been made in the management of foster home placement. The new responsibilities which have been added to the division of child welfare over a period of years have greatly increased the load on the central office and the reorganization was planned to relieve the burden there.

Personal—Dr L Mann Hartlett of Glenview state medical officer of the Selective Service System in Illinois has been promoted from major to lieutenant colonel in the Army of the United States. Col Paul G Armstrong State Selective Service Director announced on August 9. Colonel Hartlett served in the first world war in France and then entered medical school graduating from Northwestern Medical School in 1924. He practiced medicine for many years in Evanston before reentering active military service.—Dr Allan J McLaughlin, medical director U S Public Health Service Washington D C has been appointed medical administrative consultant to the Illinois State Department of Health.—Dr William I Kendall chief medical officer at the Veterans Administration Facility Bay Pines Fla has been appointed manager of the facility at Dwight, succeeding Dr Rhodrie W Browne, retired.

Chicago

Eye and Ear Infirmary to Be Affiliated with State University—The Illinois Eye and Ear Infirmary, a state institution under the jurisdiction of the state department of welfare, has been transferred to the University of Illinois College of Medicine, new papers recently reported. The transfer

was considered a step in the governor's program of improvement of public welfare service and was done to give the infirmary a larger and more comprehensive medical staff, to expand clinical work and to provide more training facilities for students and physicians. Dr. Harry S. Gradle is medical director and Dr. John B. Cipriani is managing officer of the infirmary. The infirmary was founded in 1869 by Dr. Christian Holmes, then a pioneer eye specialist in the Middle West and turned over to the state two years later. It now has a capacity of 220 beds and last year accommodated 112,000 outpatients. During the last few years the infirmary has maintained a special glaucoma service with the aid of a grant from the Ohio S. Sprague Foundation by which glaucoma patients are encouraged through the efforts of a medical social worker and a special staff of physicians to continue treatments. The infirmary also cooperated in the establishment of trachoma clinics in southern Illinois where patients from nineteen counties have received treatment.

INDIANA

Thirty Years as Head of Health Board—Dr. Herman G. Morgan was guest of honor at a dinner August 12, which marked his thirtieth anniversary as administrative head of the Indianapolis Board of Health. He was presented with a desk set in honor of the occasion. Dr. Morgan who is a native of Indiana, graduated at the Indiana University School of Medicine, Indianapolis in 1909.

Society News—Dr. Kenneth G. Kohlstedt, Indianapolis, spoke before the Gibson County Medical Society in Princeton recently on "New Developments in the Treatment of Hypertension." The Parke-Vermillion County Medical Society meeting in Clinton was addressed by Dr. Hugh L. C. Willison, Indianapolis, on "Care and Management of Venereal Diseases." Drs. Arvin Henderson, Ridgeville, and Ivan L. Biemner, Winchester, spoke on "Atelectasis" before the Randolph County Medical Society meeting in Winchester recently.

KANSAS

Annual Registration Due Between July 1 and October 1—Physicians licensed to practice medicine in Kansas are required to renew their licenses annually between July 1 and October 1 and to pay a fee of \$1 to the secretary of the board of medical registration and examination. The secretary must strike from the register of licensed physicians the names of all physicians who fail to pay their annual registration fees as required by law. Physicians whose names are so removed may be reinstated by paying the secretary \$5 and submitting to him satisfactory proof of moral fitness.

Division of Industrial Hygiene Created—The Kansas State Board of Health announced on August 24 the creation of a new division of industrial hygiene to provide consultant service for industries of the state. The Kansas Industrial Hygiene Service has, since its inception five years ago, been a part of the sanitary engineering section of the state board of health at Lawrence. Quarters for the new unit will be provided for all technical and clerical personnel of the division at Topeka in order that they may work closely with the directors of the divisions of local health service, venereal disease control and tuberculosis control. Dr. Robert M. Heilman, Lyons, Neb., U. S. Public Health Service, who graduated at the University of Nebraska College of Medicine, Omaha, in 1938, has been appointed head of the new division.

KENTUCKY

Changes in Health Personnel—Dr. Jacob Leland Tanner, Henderson, has been appointed health officer of Washington County. Dr. William R. Kelsay, Monticello, has been named health officer for Clinton and Cumberland counties in addition to Wayne county. He succeeds Dr. Paul D. Moore, Albany, who has been transferred to Casey County. Dr. Moore succeeds Dr. James T. Duncan, formerly of Columbia, who has gone to Charleston, W. Va. Dr. Donald B. Thurber, Carlisle, has been appointed director of the Tri County Health District consisting of Trimble, Carroll and Gallatin counties.

MARYLAND

Personal—Dr. Louis B. Flexner, member of the department of anatomy, Johns Hopkins University School of Medicine, Baltimore, has been given a leave of absence to serve as aide to the committee on aviation medicine of the National Research Council. The Catholic University of Chile has conferred the degree of doctor honoris causa on Dr. George W. Corner, Baltimore, director of the department of embryology of the Carnegie Institution of Washington. Dr. Lay

Martin, associate in medicine, Johns Hopkins University School of Medicine, Baltimore, is making a trip through Central and South American countries under an appointment by Nelson A. Rockefeller, coordinator of inter-American affairs.

Commander White Receives Navy Cross—Comdr. Arthur J. White, one of the senior medical officers of the aircraft carrier *Lerington*, received the Navy Cross, September 9, during ceremonies at the Naval Academy, Annapolis. Commander White was cited for his refusal to abandon ship although he had both his ankles and a shoulder fractured and numerous wounds. He was first wounded when a blast all but destroyed the dressing station he directed. Hobbled about on broken limbs, Dr. White transferred all his patients to another improvised station then had to abandon these quarters when the second blast came. According to the *New York Times* only after his last patient was removed did he consent to be lowered to the rescue ship. The medal was presented by Rear Admiral John R. Beardall, superintendent of the Naval Academy, acting for Secretary Knox on behalf of President Roosevelt. Commander White, who is now stationed at the Naval Hospital, Annapolis, graduated at Western Reserve University School of Medicine, Cleveland, in 1917.

MASSACHUSETTS

Industrial Accident Advisory Committee—A medical advisory committee has been appointed to the state industrial accident board consisting of Drs. C. Phipps, William E. Brown, Donald Munro, William A. Rogers, John G. Downing, Arl W. George and Timothy Leary, all of Boston.

Dr. Christian to Return to Teaching—Dr. Henry A. Christian, Brookline, Harvard professor of the theory and practice of physic emeritus, has been invited by the president and fellows of Harvard to return to active duty to give clinical instruction. He has also been appointed visiting physician at the Bath Israel Hospital in Boston. Dr. Christian became professor emeritus in 1939.

MICHIGAN

Advisory Committee to Crippled Children Commission—A technical advisory committee to the Michigan Crippled Children Commission has been appointed. The members are Drs. William P. Woodworth, Detroit, Frank Van Schoick, Jackson, Charles W. Peabody, Detroit, Alfred L. Arnold Jr., Owosso, Harold A. Miller, Lansing, Frederick A. Collier, Ann Arbor, and Ivor E. Reed, Detroit.

Crime Detection Laboratory Ends First Year—The crime detection laboratory, Lansing, operated by the state department of health and the state police investigated more than 200 cases during its first year. Clarence W. Muehlberger, Ph.D., is in charge of the laboratory, the maintenance of which is on an experimental basis during the first two years with the expenses taken out of the budgets of the state department of health. The legislative act which established the laboratory did not include an appropriation for its organization or operation because there was no acceptable method of arriving at cost figures until the work was actually under way.

MINNESOTA

Student Tuberculosis Survey—A total of 2,703 students were given roentgenograms in a survey recently completed by the Hennepin County Tuberculosis Association, the Hennepin County Medical Society, the department of hygiene and health education of the Minneapolis Public Schools, the Minneapolis Division of Public Health and the Minneapolis Parent-Teacher Council. The tuberculin skin test and 35 mm. x-ray examinations were offered to 3,363 graduating seniors in the public and parochial high schools of the city. A total of 2,881 students or 85 per cent of the enrolment, brought in cards signed by their parents requesting the skin test, x-ray or both. The parents of 2,272 students in this group of students indicated that they had a family physician. Of 2,642 given tuberculin tests, 811 students or 31 per cent reacted positively. Of 2,703 given x-ray examinations, 2,217 had class A (negative) results, 386 had class B (positive) results and 100 had class C (positive) results. The parents of the 100 students in class C were advised in writing to take their children to their family physician immediately for a chest roentgenogram. The parents of the 386 in class B were advised to take their children to the family physician within a year for an examination including a roentgenogram of the chest. The parents of the 526 students who had positive tuberculin tests but class A (normal) roentgenograms or no roentgenograms were advised to take their children to the family physician every year for an examination including a chest roentgenogram or a tuberculin test. Accord-

ing to the Bulletin of the Hennepin County Medical Society, the Minneapolis Division of Public Health is getting in touch with family physicians of students in group C to secure the final diagnoses

NEBRASKA

Annual Registration Due on or Before October 1—Physicians licensed to practice medicine in Nebraska are required by law to register with the Department of Public Welfare annually, on or before October 1, and to pay a fee of \$1. A license expires if the licensee fails to register, but within the thirty days next following its expiration it may be revived by the payment of the registration fee and a penalty of \$1. If that is not done, an order of revocation is issued and thereafter the revoked license can be reinstated only on the recommendation of the board of examiners in medicine and on the payment of the renewal fees and penalty then due.

NEVADA

State Medical Meeting—The Nevada State Medical Association will hold its annual meeting at Reno September 24-26 under the presidency of Dr. George R. Magee, Yerington. The program includes the following speakers:

- Dr. Thomas E. Morgan, Las Vegas: Specific Needs in the Public Health Field in the State of Nevada.
- Major Francis B. Zener, M. C. U. S. Army, Vancouver, Wash., The Physician and National Defense.
- Dr. Robert A. Peers, Colfax, Calif.: Control of Tuberculosis in the Individual Patient and Among His Contacts.
- Dr. Miley B. Wesson, San Francisco: Pyromic Disease: Etiology and Treatment.
- Dr. George W. Pierce, San Francisco: Plastic Surgery in the Region of the Eye and Orbit.
- Dr. George Joyce Hall, Sacramento, Calif.: Endocrine Treatment of Menstrual and Menopausal Disturbances.
- Dr. Warren B. Allen, Oakland, Calif.: Acute Craniocerebral Injuries.
- Dr. Bean M. Palmer, Oakland: Improved Anesthesia and Position for Perineal Prostatectomy.
- Major Louis C. Bennett, M. C. U. S. Army, Los Angeles: Diagnosis and Management of Obstruction of the Small Intestine.
- Dr. James B. Herring, Reno: Vasectomy: Its Place in Future Medicine: A Modern Operative Technique.
- Dr. Norman E. Applewhite, Reno: Sphenoiditis: Its Diagnosis and Treatment.

NEW JERSEY

Infantile Paralysis Quarantine—One block of Harper Avenue between Bull Terrace and Stuyvesant Avenue in Irvington was quarantined against infantile paralysis, September 4, after 2 cases of the disease had developed and the third was suspected, according to the *New York Times*. Health inspectors were guarding the area and no children under 17 were permitted to enter or leave the block. Adults were allowed to come and go. The *Times* reported that the health department was taking action against a stable owner in the block, as the stable was alleged to be a breeding place of flies. Household members were also being prohibited from leaving garbage in open receptacles. The 3 children involved were taken to the Essex County Hospital for Contagious Diseases, Belleville.

Museum to Exhibit Display on Nutrition—The Newark Museum will hold an exhibition on nutrition from October 1 to December 31, including a graphic treatment of community problems, the national yardstick of nutrition and consumer interests. The exhibit will use charts, photographs and large wooden cutouts, a summary of such programs as school lunches, surplus marketing plans, Red Cross and board of health work, consumer groups and nutrition councils. The national yardstick of nutrition will be demonstrated by life size figures representing a typical family of five accompanied by charts to indicate the weekly amounts of food necessary to keep up nutrition requirements. One feature will be a display of changing menus posted in the exhibit each week, offering a nutritive diet for liberal, moderate and thrifty budgets, supplied by the New Jersey Department of Agriculture.

NEW YORK

Industrial Health Teaching Day—The Medical Society of the State of New York announces 'Industrial Health Teaching Day' at Syracuse University College of Medicine, Syracuse, September 26, under the auspices of local and state agencies. The program will include the following speakers:

- Frieda S. Miller, Albany: Maintaining the Health of the Worker in the War Effort.
- Dr. Leon H. Griggs, Syracuse: Industrial Dermatoses.
- Dr. Forrest O. J. Young, Rochester: The Care of Soft Tissue Injuries.
- Dr. Donovan J. McCune, New York: Food Requirements for Health.
- Dr. James H. Sterner, Rochester: Toxic Effects of Some Newer Industrial Materials.

Refresher Courses on Venereal Diseases—A weekly series of clinical and refresher courses on syphilis and other venereal diseases will open on September 23 in the Central Social Hygiene Center, 125 Worth Street, Manhattan, and will

be continued each Wednesday morning until the series is ended. It is a continuance of the program of the bureau of social hygiene intended to keep the physicians in practice abreast of approved diagnosis of syphilis, gonorrhea and other venereal diseases. Individual topics will include the treatment of early syphilis, late syphilis, syphilis in pregnancy, congenital syphilis, chemotherapy of gonorrhea, venereal disease and the war.

New York City

Meetings on Historical and Cultural Medicine—'Public Health in New York City: Retrospect and Prospect' will be the theme of the first meeting of the fall and winter series of the section on historical and cultural medicine of the New York Academy of Medicine, November 4. The meeting will be sponsored jointly by the historical section and the committee on public health relations. Topics to be discussed include 'The Story of the Public and Voluntary Health Agencies' and 'Glimpses Into the Future'. The following program has been announced for meetings of the historical section, which are held bimonthly: Drs. Henry E. Sigerist and Arturo Castiglioni, Baltimore, who will speak on 'Vesalius,' January 13, and Dr. Edward Rosen, Revere, Mass., 'Copernicus,' March 10.

OHIO

Annual Forum on Allergy—The fifth Annual Forum on Allergy will be held at the Hotel Statler, Cleveland, January 9-10. Information may be obtained from Dr. Jonathan Forman, 956 Bryden Road, Columbus.

Museum Receives Grant for Nutrition Exhibit—The Cleveland Health Museum has received a grant of \$1,100 from the Thomas H. White Trust Fund to establish a permanent exhibit on nutrition and health at the museum. The exhibit is expected to open early in January.

Personal—Dr. Thomas F. Ross, Columbus, has been appointed medical director of the Ohio State Life Insurance Company. More than one hundred and seventy-five friends and colleagues recently gathered to honor Dr. Henry J. Pellevé, Hanoverton, on the fiftieth anniversary of his graduation from medical school. Dr. Robert H. Hoecker has resigned as health commissioner of Mount Vernon to enter army service. Dr. Frank M. Hartsook, Cardington, has been named health commissioner of Morrow County.

OKLAHOMA

Executive Secretary Graham Goes to Procurement and Assignment Service—Robert H. Graham, Oklahoma City, executive secretary of the Oklahoma State Medical Association, has been granted a leave of absence to serve as executive assistant to Lieut. Comdr. Maxwell E. Lapham of the Procurement and Assignment Service. Miss Ann Betche, assistant secretary, will carry on the work of the executive office.

University News—Dr. Willis Kelly West, associate professor of orthopedic surgery, University of Oklahoma School of Medicine, Oklahoma City, has been appointed acting chairman of the department of orthopedic surgery and acting chief of the orthopedic service in the University and Crippled Children's Hospitals. Dr. Paul C. Colonna, who was in charge of these units, resigned to become professor of orthopedic surgery at the University of Pennsylvania School of Medicine, Philadelphia.

PENNSYLVANIA

Scranton Mothers in War Industries—Lanham funds for war nurseries and child care projects made available early this year are making possible a program of before and after school care, noon lunch and vacation care for 100 children in the first to seventh grades of Scranton schools, newspapers report. September 1. The Scranton project was applied for after a survey revealed that of 375 mothers in the Scranton school district, 170 are employed, leaving their children without proper care except during the regular school hours. The mothers are working in companies handling war orders. Care for the school age children will be available five days a week. In winter the program will be operated in the schools from 6:45 to 8:30 a. m. and from 3 to 5:30 p. m. and will provide a noon lunch for the children of war workers. During the summer when the city's normal recreation program extends to 4 p. m. the program will operate from 4 to 9 p. m. and lunch will be served at noon.

Health Institute—The Third Pennsylvania Health Institute will be held at the Penn Harris Hotel, Harrisburg, September 28-30, under the auspices of the division of health education of the state department of health and a group of

national and local agencies. Included among the speakers will be representatives from the army, navy and public health service. Other speakers will include

Sister Elizabeth Kenny Minneapolis Infantile Paralysis—The Cripple
Dr. Charles Howard Marcy, Pittsburgh Tuberculosis and the Home
Front
David J. McDonald Pittsburgh Labor's Stake in the Control of Health
Hazards
Dr. Joseph Shulen Pittsburgh Influence of Occupation on Tuberculosis
Col. John J. Moorhead M. C. U. S. Army, New York Surgical Service
at the Pearl Harbor Attack
John W. German Jr. Harrisburg The Importance of Medical Exam-
nation in the Schools
Dr. Herbert T. Kelly Philadelphia Nutrition and the War Effort
Dr. William H. Brennen Meadville Community Health Hazards
Accompanying the War Effort

RHODE ISLAND

The Charles V. Chapin Annual Oration—The Rhode Island Medical Society has established the annual Charles V. Chapin Oration in honor of the late Dr. Chapin, who throughout his entire career was active in the field of public health in Rhode Island and Massachusetts. Dr. Timothy Leary, professor of pathology emeritus, Tufts College Medical School, Boston, recently gave the first lecture on "Atherosclerosis—Its Causes." Dr. Chapin, who died in 1941, had been superintendent of health of Providence from 1884 to 1932 and lecturer at Harvard School of Hygiene and Public Health from 1923 to 1935. In 1914 he carried on a survey of state sanitation throughout the United States for the American Medical Association. In 1927 he was president of the American Public Health Association.

VERMONT

New Professor of Pharmacology and Physiology—Dr. Donald H. Slaughter, formerly associate professor of pharmacology at Baylor University College of Medicine, Dallas, has been appointed professor of pharmacology and physiology and chairman of the department of the University of Vermont College of Medicine, Burlington.

Director of Maternal and Child Hygiene Appointed—Dr. Viola Russell, director of maternal and child hygiene of the North Dakota State Department of Health, Bismarck, has been appointed to a similar position for the Vermont Department of Public Health in Burlington. She had held the North Dakota position since Jan. 1, 1940.

WASHINGTON

Personal—Dr. Robert W. Ripley, New York, recently arrived in Paseo to serve as assistant district health officer for Benton and Franklin counties and the western top of Walla Walla County.—Dr. Eugene L. Kidd, Centralia health officer of Lewis County, has been placed in charge of the unit in Snohomish County with headquarters in Everett.

GENERAL

Clinical and Climatological Association Postpones Meeting—The American Clinical and Climatological Association announces the postponement of its annual session, which was scheduled for Princeton, N. J., October 12. Dr. Francis M. Rackemann, 263 Beacon Street, Boston, is the secretary.

Statistical Information on Diabetes—The American Diabetes Association has appointed a committee on statistical information to set up procedures for the collection of data for future analysis. The action was taken at the recent annual meeting of the association with a view toward developing a plan for the future welfare of the diabetic in the general public health program.

Hard of Hearing Week—The American Society for the Hard of Hearing, Washington, D. C., will sponsor the observance of National Hearing Week, October 25-31, to acquaint the public with the causes of deafness and the need for guarding against them. One hundred and sixty local societies for the hard of hearing in the United States and Canada will participate. "Keep 'Em Hearing" is the theme of the observance this year.

National Safety Congress—"Save Manpower for War-power" will be the theme of the thirty-first National Safety Congress and Exposition, to be held in Chicago October 27-29. The entire program, covering every phase of safety with one hundred and seventy-five sessions and five hundred program participants, will be centered on the problem of stopping accidents that delay victory by slowing production, impeding the movement of troops and supplies and wasting manpower, material and time.

Public Health Officers—Dr. Karl F. Meyer, San Francisco, was chosen president-elect of the Western Branch of the American Public Health Association in Seattle recently, and Dr. Donald G. Evans, Seattle, was installed as president. Vice presidents are Dr. Adolph Weinzirl, Portland, Ore., Benjamin V. Howe, Denver, and Dr. Claude E. Dolman, Vancouver, British Columbia. William Ford Higby, San Francisco, is the secretary and Guy S. Millberry, D. D. S., Los Gatos, Calif., treasurer.

Society News—Officers of the Medical Library Association chosen at its recent annual meeting in New Orleans are Mary Louise Marshall, New Orleans, president, Dr. John F. Fulton, New Haven, vice president, Frida Pfeiffe, Rochester, Minn., secretary, and Bertha B. Hallam, Portland, Ore., treasurer.—The annual meeting of the National Association of Coroners will be held in conjunction with the session of the Pennsylvania State Association of Coroners in the Roosevelt Hotel, Pittsburgh, November 16-18, under the presidency of Alexander L. Brodie, Chicago, coroner of Cook County.

Motion Picture on Peptic Ulcer—The first complete movie film on peptic ulcer in color and with sound track is now available for free showings to groups of physicians. The film is entitled "Peptic Ulcer" and was produced under the direction of the department of gastroenterology of the Lahey Clinic, Boston. Running time of the film is forty-five minutes. There are 1,600 feet of 16 mm. film, which covers the following problems of peptic ulcer: pathogenesis, diagnosis, treatment, pathology complications, including obstruction, hemorrhage and perforation, gastric ulcer, surgery and jejunal ulcer. Arrangements for a showing of the film may be made by writing to the professional service department of John W. Eth and Brother, Inc., Philadelphia, who will provide projection equipment, screen, film and operator for medical groups without charge.

Medal Awarded to Health Administrator—Miss Emily P. Bissell, Wilmington, Del., originator of the Christmas Seal sale in the United States, recently was presented with the Trudera Medal of the National Tuberculosis Association. The medal established in 1926 in memory of Dr. Edward Livingston Trudera is awarded annually to the person who in the opinion of the award committee of the national association has made a "meritorious contribution to the cause treatment or prevention of tuberculosis." Miss Bissell is the first person in administrative work in the tuberculosis field to receive the medal and the second woman to be thus honored. In 1938 Florence B. Seibert, Ph.D., Philadelphia, received it for work on the purification and standardization of tuberculin. Miss Bissell has long been active in developing improved programs for children and in 1904 aided in forming the Delaware chapter of the American Red Cross. In 1907 she took steps to found a tuberculosis seal movement similar to the program in Denmark. A sum of \$3,000 was raised in the first sale, part of which went to the purchase of 50 acres of land, on which a sanatorium was built. Miss Bissell was active in the creation of a state tuberculosis commission and became president of the Delaware Anti-Tuberculosis Society, a position she still holds.

CANADA

President of Canadian Medical Association—Dr. Albert E. Archer, Lamont, Alta., was elected president of the Canadian Medical Association at its annual meeting in Jasper, June 17, succeeding Dr. Gordon S. Fahrni, Winnipeg, Man.

Hospital Observes Terecentenary—The Hotel-Dieu de St. Joseph, Montreal, Que., celebrated its three hundredth anniversary in June. The Canadian Hospital Association and allied groups joined in holding a special celebration, and greetings were received from the hospital associations of the United States in honor of the event.

LATIN AMERICA

Personal—Dr. Julio C. Garcia Otero was reelected dean of the Faculty of Medicine of Montevideo, Uruguay, recently.—Dr. Eduardo Escudero Santiago was appointed minister of public health and social welfare of Chile.—Dr. Cesar Gordinillo Zuleta, Lima, has been appointed general director of public health of Peru.

FOREIGN

Personal—Dr. John W. H. Eyre, emeritus professor of bacteriology of the University of London since 1935, has been elected president of the Royal Institute of Public Health and Hygiene to succeed the late Sir Thomas Oliver.

New Medical Journal—The first copy of the *Annus Lusitanus*, Lisbon, Portugal, a journal of medicine and surgery has been received. The first issue, dated December 1941, contains eighty pages of original articles, clinical notes and book

reviews Dr Reinaldo dos Santos is editor of the journal, the address of which is Livraria Portugal, Rua do Carmo, 7° Lisbon

British Association Rejects State Medicine—The British Medical Association on September 9 rejected by a vote of 177 to 20 a proposal to have it endorse the establishment of a full time salaried government medical service, according to the *New York Times*. It was voted 94 to 92 that any postwar service embracing medical centers should be made available everywhere. The *Times* reported that Sir Kaye Le Fleming said "salaried physicians and surgeons would lose their liberty for all time and become servants of the government, which has never shown any great interest in the welfare of the medical profession." He is further reported to have said that "neither the public nor the profession wants such service and the government is not anxious to start it if it can be helped." The association adopted an amendment recommending that a patient should have the right to contract outside the medical center plan and that a doctor could charge fees for attendance on patients not on his list.

CORRECTION

Chief of the Division of Neuropsychiatry—In the announcement of the assignment of Dr Roy D Halloran to the U S Army Surgeon General's Office, Washington, D C, in THE JOURNAL, September 5, page 57, his title should have been correctly stated as follows: Colonel, Medical Corps Army of the United States Chief of the Division of Neuropsychiatry, the Surgeon General's Office

SPECIAL NEWS

(THIS NEWS WAS ASSEMBLED ESPECIALLY FOR USE IN THE JOURNAL)

Health Under Hitler—According to the *Frankfurter Zeitung* of June 23, Conti made a statement that "reports from numerous observations show that many sick people get extra food rations on doctors' recommendations in order to assist their convalescence or working capacity but do nothing themselves to hasten their convalescence by their way of living. Many people, for instance, do not refrain from smoking, which is bad for some illnesses, some of which are undoubtedly caused and made worse or at least prolonged by smoking. In such cases, to grant special food rations is a waste at the expense of the German people. In view of the food situation, that is not only inequitable but intolerable." Having given a few examples Conti continues "I therefore request all doctors to devote their greatest attention to this matter. It is part of the doctor's duty to draw the attention of his patients to the interdependence of these things, and it is part of the doctor's right to refuse extra rations for patients if the latter do not assist the doctor's efforts by their way of living. This should be the general rule, but it applies particularly to smoking."

At the station of La Louviere a crowd of 100 people assailed a train loaded with coal, according to *La Legia*, Liege. July 6 and several tons of coal were stolen. Incidents of this kind occur frequently, in spite of the repeated intervention of the gendarmes.

The *Volk en Staat*, Antwerp, of July 13 reports that the fat supply is Belgium's hardest problem. "The attempt to increase the production of oleaginous seeds has failed. Our farmers prefer to cultivate tobacco, sugar and beets, which are more profitable. Why are our farmers not forced to cultivate a minimum of oleaginous seeds as the Dutch farmers are? The ploughing up of pastureland has been sadly neglected, there too better results could be obtained. Considering the number of cattle we have left, we hardly need so much pastureland."

According to *Svenska Dagbladet*, Stockholm, of July 13 the Norwegian police authorities have started a large scale mustering of bicycles belonging to Norwegian civilians. It is believed that the Germans will requisition thousands of Norwegian bicycles. Recently hundreds of Norwegian motor car workshops were requisitioned by the Germans and forbidden to carry out civilians repairs.

According to *Akropolis* Athens, of July 9 it is reported that chemists refuse to make up prescriptions for those customers who look poor and likely to be unable to pay the enormous prices for medicines, which have increased by 400 per cent in the last month.

Government Services

Warning About Veterinary Anthelmintics

The Federal Food and Drug Administration has issued a notice to manufacturers of veterinary anthelmintics and users of the preparations that all known effective anthelmintics are more or less toxic to animals. These preparations should not be administered to sick, physically weak or undernourished animals unless on the advice of a veterinarian. The Federal Food, Drug and Cosmetic Act requires that drugs be labeled with adequate directions for use and adequate warnings against misuse. It defines as misbranded drugs which are dangerous to health when used in accordance with the direction provided in the labeling. To avoid conflict with the requirements of the act, these provisions should be given careful consideration.

New Assistant Chief of Economics

Hazel K Stiebeling, PhD, formerly head of the family economics division U S Department of Agriculture has been appointed assistant chief of the bureau of home economics of the department under Louise Stanley PhD chief of the bureau. Dr Stiebeling will have charge of the research work carried on in the field of home economics which is now integrated with that of other scientific agencies in the department through agricultural research administration. Dr Stiebeling has been interested primarily in nutrition and perhaps her greatest single contribution has been the application of methods for determining the dietary levels of groups of people.

North Carolina Free of Brucellosis

The U S Department of Agriculture announced on July 6 that North Carolina is the first state to be officially designated as a modified accredited Bangs disease free area. This state also was the first in which all counties were declared practically free of bovine tuberculosis in 1928. The last ten counties in North Carolina were among the twenty eight added to the areas officially designated as modified Bangs disease free areas by the U S Bureau of Animal Industry and cooperating state officials, July 1. These counties are in twelve states and contain approximately three hundred and seventeen thousand dairy and breeding cattle 6 months of age and older. With this latest addition the 'modified' area includes a total of five hundred and fifty counties in twenty four states. Bangs disease (brucellosis) eradication work is being conducted on the area in about one hundred and sixty additional counties. A county may be officially designated as a modified accredited area when a test for Bang's disease has been applied to all cattle 6 months of age or older, except steers, and the percentage of reactors to the last test does not exceed 1 per cent of the cattle and the infected herds do not exceed 5 per cent of the total number. When a county meets these requirements it may be declared a modified accredited Bang's disease free area for three years.

Tuberculosis Section Created

A tuberculosis control section has been established in the States Relations Division to cooperate with the Division of Industrial Hygiene, National Institute of Health Bethesda, Md. The new section will assist in carrying out the tuberculosis control program which includes an examination of U S Coast Guard recruits workers in war industries, persons in war industries communities and the elaboration in cooperation with selective service the navy and state health departments, of a system of reporting cases of young men rejected because of tuberculosis. A consultation service will be available to state health departments in the development of control programs and 35 mm photofluorographic x-ray units are being lent to the bureaus of industrial hygiene and the bureaus of tuberculosis control in case finding. The service includes a medical officer trained in interpreting 35 mm films a technician and a clerk. According to the *Veterinary Surgeon* one unit is in operation in North Carolina, another in San Antonio, Texas, and a third at the Curtis Bay Coast Guard Station near Baltimore. The fourth unit will soon be placed in operation at the Coast Guard Station at Sheepshead Bay, Long Island, N Y. Other units are expected to begin work in Illinois and Kansas within the next few months.

New Type of Stretcher for Merchant Ships

The ministry of war transport has issued a description of a new type of stretcher for use in the merchant navy. This follows the decision of the joint advisory committee on the health of the mercantile marine that at least two of these stretchers shall be carried on all foreign going merchant ships. This type of stretcher, which is called "the Neil Robertson," is especially efficient because the patient can be carried in it under difficult conditions without being liable to roll or slip out at whatever angle it is carried. It is a simple apparatus for moving the wounded safely from difficult places where the ordinary stretcher with stiff poles would be useless. The man is enveloped in a protective but flexible case so that he takes up as little room as possible. He is wrapped up like a mummy, to be hoisted vertically or carried horizontally. The stretcher can be bent slightly in turning sharp corners in narrow passages, as when it is being loaded up the ladderways from stokeholds or engine rooms. The stretcher is made of stout canvas 65 inches long, the whole being stiffened by bamboo slats sewn to the canvas. It has proved of great value not only on board ship but in other places where an injured person has to be extricated from an awkward position.

Precautions Against Gas Attacks on Civilians

Precautions are being taken against an attack on our civilian population with "blister gas" (mustard gas, or lewisite). A leaflet on the subject has been distributed, and persons splashed are entitled to enter any house and demand soap and water to wash off the poison. They are told that there is no need for alarm if they know what to do. The gas mask will protect such vital parts as the eyes and lungs and so should always be kept handy, even when in bed. An anti gas ointment (bleach cream) is prepared by all pharmacists, who are ordered to have a pail of it outside their shops if gas attacks take place. Persons splashed on skin or clothing should take off the splashed garments, apply the anti gas ointment immediately to the affected part, dab it off with a rag (not wipe it off, which might spread the poison), and rub the anti gas ointment into the place. The rag should be burned. If within five minutes' walk of a house one should go there, discard the remaining outer clothing before entering and have a wash down and a change of clothing. If no such place is available one should go to the nearest public gas cleansing center or first aid post with a gas cleansing section. Those who admit splashed persons to their houses are instructed to see that they take off their shoes and outer clothing before entering and that they do not touch anything with hands or clothing before they reach the washing place. If the eyes are splashed they should be thoroughly flushed out with warm water immediately. If the hair is splashed it should be cut off and anti gas ointment rubbed into the scalp. Discarded clothing is to be sent to the local decontaminating center.

The Drying of Plasma and Serum

The trustees of the late Sir Henry Wellcome have placed \$100,000 at the disposal of the Medical Research Council for research into methods of drying blood plasma and serum to provide stable products for use in the transfusion of patients suffering from hemorrhage, shock or other conditions. The trustees and the council have agreed that the gift is to be used for the purchase, erection and operation by the council of a plant to test and develop these methods on a large scale. As

the need for improvement of such methods is so important just now and the products will be made freely available for the treatment of the sick and wounded, the council has expressed appreciation of this timely and humanitarian action of the trustees.

A Professorship of Social Medicine

The Nuffield Provincial Hospitals Trust (founded by the automobile magnate Lord Nuffield), will devote \$50,000 a year for ten years to the creation in Oxford University of a professorship of social medicine and the foundation of an institute in which the professor will work. The purposes of the institute are (1) to investigate the influence of social, genetic, environmental and domestic factors on the influence of disease, (2) to promote measures other than those usually employed in remedial medicine for the protection of the individual and the community against such forces as interfere with the full development of man's mental and physical capacity, (3) if required by the university, to provide for the instruction in social medicine of students and physicians.

The university registrar of Oxford points out that the public is hardly aware of the progress in the last few generations in the prevention of disease. Smallpox has been virtually eliminated from this country by vaccination, typhus by rise in the standard of cleanliness, cholera by purification of the water supply, bubonic plague by the control of ship borne rats, and typhoid by the scientific treatment of sewage. But the fact remains that in the last year before the war 256 million working weeks were lost by the insured population. The prevention of disease appeals much less to philanthropists than the cure, which is so much more striking. Hence they have been less ready to give money for prevention. Six years ago Lord Nuffield devoted \$10,000,000 to the endowment of medical research at Oxford and later increased this by \$3,000,000 for special purposes. With this money a great school of research into the causes and treatment of disease has been set up. One result of the foundation was to concentrate attention on the need for the study of prevention. In this, social medicine is a new field and Lord Nuffield's latest gift specially provides for it.

Smaller Medical Journals

The war has cut off the Scandinavian sources of material for making paper, and the supply of paper for the printing of periodicals and books is controlled by the government. The result is enforced economy in the consumption of paper. The first June issue of the *British Medical Journal* in 1941 contained only thirty-eight reading pages, in the corresponding issue of 1942 the number was reduced to thirty-two because the paper controller continues to cut the supply. Hence the *British Medical Journal* has made a further reduction in the size of the type and reduced the considerable space given to correspondence, and has enjoined conciseness on correspondents.

Britain's Food Problem in the Future

At the annual meeting of the chemical industry Sir John Russell, director of the Rohmstedt Experimental Station (agricultural) and of the Imperial Bureau of Soil Science, who was presented with the society's Messel medal, spoke on chemistry and agricultural reconstruction. Some measure of planning must come into our national life after the war, and this was particularly true of agriculture. Our prewar conditions had given us the richest and most varied dietary in Europe—so rich and varied that only 40 per cent was produced here and the remainder imported. Anything like the same standard after the war could be attained only by careful planning at home and well designed arrangements with overseas exporting countries. One advantage would be more effective use of science. The problems of reconstruction included the more efficient use of fertilizers and feedstuffs, the closer relation of food production on the farm to considerations of national health and

nutrition including that of animals, and the need for fuller cooperation between agricultural experts and those responsible for working up the produce into its final form.

Perhaps the most difficult problem of the future would be to preserve the freedom of the scientific worker, without which scientific progress was impossible, and at the same time to insure the application of science to the problems of industry and agriculture. The Nazi system had been detrimental to the progress of pure science in Germany, yet it had insured successful applications of science at any rate to activities related to war. We, on the other hand, had been much more successful with pure science. Our problem was to obtain equal success in its application.

Death of the Author of the Index Animalium

Dr Charles Davies Sherborn, who has been on the staff of the British Museum of Natural History since 1886, when its director was the celebrated Richard Owen, the protagonist of Darwin, has died in his eightieth year. His published works, particularly his great *Index Animalium*, are a monument to his unique services to the bibliography of zoology and paleontology. In 1888 he published "A Bibliography of the Foraminifera" and in 1896 "An Index of the Genera and Species of the Foraminifera." He collaborated with Sir Arthur Smith Woodward in "A Catalogue of British Fossil Vertebrata." In 1890 he put forward his scheme for an *Index Animalium*, a gigantic task which was to occupy most of his time for forty-seven years. His object was to provide naturalists with complete lists of all the generic and trivial names of animals since the time of Linnaeus and the date and place of publication of each name. The colossal nature of his task is shown by the fact that the entries ran to more than four hundred thousand, all of which he extracted from the original sources except two thousand from books not available to him.

MEXICO

Aug. 10 1942

Outbreak of Typhoid in the Federal District

Year by year, typhoid and paratyphoid fevers, which are endemic all over Mexico, show a slight increase during the beginning of the rainy season, but since last year the number of cases registered has been unusually high and the diseases have spread all over the Federal District, particularly in certain quarters of Mexico City. Well water is used in some towns, especially Tacuba and Atzacapotzalco. These quarters are located in the west of Mexico City. Examination of 2,627 samples of water from the public system showed pollution in 125 per cent, and 100 per cent of 399 well waters were found heavily polluted. Several samples of lemonade and ice cream from different factories and other refreshments have been found contaminated and their sale has been prohibited. Ice used for various purposes has been found polluted. It is considered by the epidemiologists that the main cause for the outbreak has been the pollution of the water supply system from the careless change of broken pipes either from the sewerage system or from the water supply. In certain zones of the Federal District the 'antojitos Mexicanos' (Mexican delicatessen) especially those sold by vendors and in open air kitchens are to be blamed also. The case fatality rate registered has been 14 per cent. Taking into account unnotified, missed and ambulant cases it is estimated that over 2,500 cases have occurred from August 1941 up to July 1942.

The notification of cases of communicable diseases has been enforced and several practitioners have been fined for not reporting the cases under their care. Health authorities have carried on in addition propaganda and health education through visiting nurses about measures to control the outbreak, i. c. com-

pulsory laboratory examination of water and refreshments in restaurants, prohibition of selling certain Mexican foods, fight against flies and vermin and immunization. The number of persons immunized during the present year has been about 250,000. The people have not offered any resistance toward immunization and willingly attend the clinics for the four doses used in Mexico.

The Problem of Leprosy

According to the third quinquennial census 6,190 lepers exist in the republic of Mexico. The principal focuses are located in the Federal District, in the state of Guanajuato in the central plateau, in the states of Jalisco and Sinaloa in the midwestern coast and in the state of Yucatan in the southeast. During the taking of the census, 338 new lepers were discovered. Only 221 lepers are isolated in the Lepers' Home "Dr. Pedro Lopez" in Zouquapam, in the outskirts of the Federal District. Another leprosarium is being built in Sarabia, state of Guanajuato, on which about half a million Mexican pesos have already been spent.

During the survey 1,326 relatives of those lepers were found. In the Bureau of Leprosy 20,551 relatives or persons closely connected with lepers are registered and last year 9,038 individual examinations were carried out among relatives and 117 new lepers were discovered.

In accordance with the records of the Bureau of Leprosy, Division of Epidemiology of the Federal Department of Health, 1,715 lepers were treated with chaulmoogra oil derivatives, "Mercado Mixture" and other medicines. Of those 737 improved and 183 are in worse condition. No improvement whatever was obtained in 632 cases, and from 163 there is no report available.

The Bureau of Leprosy has increased its activities, organizing twenty-one new branches or local leprosy councils in different municipalities, and new clinics have been established. The first Dispensario Antileproso "Dr. Rafael Lucio" was inaugurated in Mexico City in 1930.

Late last year the first Conference on Leprosy held meetings in Guanajuato City and nineteen papers dealing with the problem were presented, most of them on the subject of proper isolation of lepers in "ad hoc" institutions.

During the present year the Federal Department of Health, in cooperation with the Secretariat of Public Assistance, organized a special course on leprosy for the physicians in charge of the different aspects of the fight against it. The lectures were in charge of fourteen of the most prominent leprologists in the country headed by Dr. Jesus Gonzalez Ureña. In addition, fourteen leprologists from all over the country held a meeting in March at the Federal Department of Health to set the basis for research, prophylaxis and treatment during the coming years. During this meeting the National Society of Leprology was organized.

Protection of Civilians in the National Defense

Authorized by the national congress, President Avila Camacho has issued regulations to protect the civilian population during the present war. Safety measures include detecting airplane services, alarm, camouflage devices, blackout, fire services and air raid and gas shelters. Social assistance regulations deal with all medical and surgical activities in case of an emergency. These activities will be in care of official and private institutions.

The Secretariat of Public Assistance will take care of all evacuees, the building of camps, the organization of emergency hospitals and the distribution of food, medicine and other public assistance services. The Federal Department of Health, in cooperation with the civilian authorities, is in charge of all preventive activities, particularly in case of evacuation of mothers, children and aged persons, sanitation of camps and lodges for evacuees, sanitation of food and water and prevention of communicable diseases.

BUENOS AIRES

Public Health in Bolivia

Dr. Abelardo Ibañez, minister of public health in Bolivia, recently presented a report to the national congress in which he indicated the factors which are a menace to public health. The population is very sparse. The rural population in the Chaco region emigrated to the cities after the Chaco war. Previously they had lived in plateaus and mountains where there was no tuberculosis. Now they live in crowded areas near the cities and many of them have tuberculosis. The number of hospitals is insufficient. Malaria is frequent, for instance, in Cochabamba 3 or 4 cases a year were reported, but last winter more than 300 cases were seen. Yellow fever and pestilential diseases appear in sporadic epidemic outbreaks in isolated regions. Several animals in the forests are the agents in transmitting the diseases. Many cases of leprosy are observed in some regions of the country. Goiter is endemic. Intestinal parasitism, especially ancylostomiasis, exists in 98 to 100 per cent of children and adults in the tropical and subtropical regions. The epidemics of exanthematic typhus are grave every year. During the last few years the number of cases of recurrent typhus has increased. Venereal diseases have increased during the last few years. Ninety per cent of the people suffer from hunger and chronic avitaminosis. The government has taken steps to control the unfavorable sanitary conditions. A campaign of preventive and curative medicine all through the country is in progress. Many hospitals are urgently needed. Two central hospital-sanatoriums are to be constructed in La Paz and Cochabamba, according to a decree of the government. There is a department of the state for prevention and control of pestilential diseases and an organization of the state and the Rockefeller mission for prevention and control of yellow fever. The department of viscerotomy against yellow fever and the department against pestilential diseases are well organized and have their own means for transportation. The government made an appropriation of money in the 1942 budget for the construction of a leprosarium in San Silvestre Island, Mamore River. The systematic delousing of natives is already established. Typhoid has diminished because of the systematic administration of antityphoid vaccine. Few cases of smallpox, if any, are observed. A department for prevention and control of venereal diseases is functioning. The treatment of patients during the contagious period is obligatory. In May 1941 an institution for nutrition was opened to the public. It has four departments, one of which is in charge of the free distribution of milk and lunches to school children. The government is giving constant attention to the various problems of public health.

Gold Salts in Chronic Articular Rheumatism

Gold therapy prevents the development of new articular lesions in chronic deforming arthritis, according to Dr. G. Costa Bertam of Buenos Aires, who reported his observations in 45 cases (*Rev. argent. de reumatol.* 6:159 [Oct.] 1941) in which the therapies commonly resorted to had previously failed. Gold therapy produced great improvement in 40 cases and moderate improvement in 5 cases. The treatment has specific effects on inflammation but not on the deforming lesions, which should be independently treated especially with physical therapy. The good effects of gold salts on rheumatic deformities rest on the previous elimination of the septic rheumatic foci which produce the articular deformities. Gold therapy should be administered with caution, because patients with rheumatism are hypersensitive to the substance. The treatment is contraindicated when examination of the patient shows blood disease.

Intramedullary (Sternal) Transfusion

At a recent meeting of the Société de science médicale et biologique de Montpellier, Prof. Gaston Giraud, the new dean of the Faculty of Medicine at Montpellier, discussed a case of hemorrhagic aleukemia treated by means of intramedullary transfusion performed for the first time in France. A woman aged 25, after chrysotherapy, has shown a hemorrhagic syndrome with extreme anemia and medullary aplasia. In spite of repeated blood transfusions, genital hemorrhages have occurred daily and the anemia has been progressive. An intra-medullary transfusion of 1 cc of sternal marrow from the patient's mother was performed. Two hours after transfusion the hemorrhages had nearly ceased. The next day the fever ceased and the number of platelets increased but on the third day the hemorrhages reappeared. Three days after the first transfusion the second was made. Four days after the second transfusion a third was made, after which a progressive improvement occurred. But in this case Giraud emphasizes with Fraser, Bavis, Drummond, Menclrier, Aubertin and Weill the necessity of prolonged medullary opotherapy in order to obtain a stable blood condition in the treatment of certain cases of isochromatic anemia with leukopenia and neutropenia. Medullary opotherapy has been continued during two months and a half, at the end of which the blood elements have become nearly normal.

At another meeting of the society Professor Janbon, Dr. Chaptal, Mlle. Labraque-Bordenave and Dr. Bose discussed a case of granulocytopenia occurring after treatment with 26 Gm of sulfapyridine in five days and after three days 28 Gm in nine days for relapse of a meningitis with meningococcus A in a severe form with septicemia and generalized purpura. On the sixteenth day of the treatment an alarming granulocytopenia developed. The number of hematis and platelets remained normal, there was no tendency to hemorrhage. From the first twenty-one days the sternal marrow showed only 10 per cent of blood elements of the granulocyte series. The general state got rapidly worse. The fever reached 102.2 F and there were muscular cramps (without meningitis symptoms). On the twenty-third day an intramedullary transfusion was made. 2 cc of sternal pulp from a universal donor was injected into the sternal marrow of the patient. A gradual decline of the fever and a general improvement followed. From the twenty-fifth day the sternal marrow appeared to be rich in elements. On the twenty-seventh day eosinophils reappeared in the blood. The polymorphonuclears were between 45 and 55 per cent and numbered 3,500 to 4,300. The intramedullary transfusion was supported by special treatment. Janbon suspected a tissue blockade due to the sulfapyridine and tried to clear this blocking by means of bengal rose. A massive elimination of 5,100 Gm of sulfapyridine was obtained through the urine in twenty-four hours, the day before, this urine elimination was only 100-200 mg in twenty-four hours. Janbon believes that the amount of sulfapyridine was thus diminished in the sternal marrow and that conditioned the success of the intramedullary transfusion.

Marriages

RALPH L. DICKER, Jersey City, N. J., to Miss Shirlev C. Banks of North Bergen, in New York, March 1.

RICHARD BETRUS ELGOSIN to Miss Betty Rosemary Messer, both of Waterbury, Conn., June 29.

GRAY CARLTON HUGHES, Martinsville, Va., to Miss Meta L. Inman of Kingstree, S. C., June 6.

J. WALLACE FINDLEY, Graham, Mo., to Miss Mary Virginia Covington of St. Louis, June 27.

Deaths

Owing to the accumulation of material of military importance, the publication of obituaries has been somewhat delayed, hence the publication of four pages in this issue

Henry Rawle Geyelin * New York, University of Pennsylvania School of Medicine, Philadelphia, 1909, instructor of clinical pathology at the Columbia University College of Physicians and Surgeons from 1913 to 1916 associate in clinical pathology, 1916-1917, associate in medicine from 1917 to 1921 and since then assistant clinical professor of medicine, specialist certified by the American Board of Internal Medicine, member of the American Association for the Advancement of Science, the Association of American Physicians, the American Clinical and Climatological Association, the American Society of Clinical Investigation and the Harvey Society, fellow of the American College of Physicians, since 1921 associate attending physician at the Presbyterian Hospital, where he was formerly a Blumenthal fellow in medicine and assistant visiting physician, chief of the medical clinic of the Vanderbilt Clinic, 1918-1919, consulting physician at the Babies Hospital from 1923 to 1928, visiting physician from 1928 to 1932 and since 1933 associate attending physician, consultant specialist in diseases of metabolism at the U S Veterans' Hospital number 81 from 1924 to 1933, member of the medical board of the Doctors Hospital since 1929, aged 58, died, September 7

Thomas Dyer Tuttle, Chula Vista, Calif., College of Physicians and Surgeons, New York, 1892, member of the House of Delegates of the American Medical Association in 1910 and 1911, for many years secretary and state health officer of the Montana State Board of Health, past president and vice president of the Medical Association of Montana, in 1904 organized the Montana Public Health Association and served as the first secretary, served as director of medical administration of cantonments of Fort Lewis and Bremerton, Wash, with rank of major during World War I, formerly on the staff of the U S Veterans Hospital number 65 at St Paul, was instrumental in the building and was the first superintendent of the Montana State Tuberculosis Sanitarium, Galen, in 1911 was awarded the first Ricketts Memorial Medal by the Medical Association of Montana, wrote the food and drug law which was passed by legislature in 1911, was successful in securing the enactment of the stream pollution and sewage disposal law in 1907 and wrote and secured passage of the general public health law, aged 73, died, June 24, of heart disease

John Cowell MacEvitt, Brooklyn, College of Physicians and Surgeons, Keokuk, Iowa, 1878, member of the House of Delegates of the American Medical Association in 1911 and from 1913 to 1915, member of the Medical Society of the State of New York, president of the Medical Society of the County of Kings in 1910, past president of the Brooklyn Gynecological and the Brooklyn Pathological societies, fellow of the American College of Surgeons, served as a passed assistant surgeon in the U S Navy during the Spanish-American War, was a senior medical officer with rank of lieutenant commander in charge of four naval air stations at Brest, France, during World War I, for many years a member of the medical staff of St Mary's Hospital, where he was chief of the gynecologic service and president of the medical board, formerly chief gynecologist at the Coney Island Hospital, at one time editor of the *New York State Journal of Medicine*, aged 86, died, July 1 of cerebral arteriosclerosis

Alfred Merriman Rowley, St Petersburg, Fla., University of Vermont College of Medicine, Burlington, 1897, specialist certified by the American Board of Surgery, member and past president of the New England Surgical Society, fellow of the American College of Surgeons, at one time a medical inspector for the board of health of Hartford, Conn., served as a major with the American Expeditionary Forces during World War I and received a special citation from General Pershing for his service as a member of the Yale mobile hospital unit in France, consulting surgeon at the Hartford (Conn) Hospital, the Hartford (Conn) Retreat the Charlotte Hungerford Memorial Hospital (Torrington, Conn), the Manchester (Conn) Memorial Hospital, the Rockville (Conn) City Hospital, the Bristol (Conn) Hospital, the New Britain (Conn) General Hospital and the Veterans Administration Facility, Newington, Conn., aged 66, died, July 20

Adelaide Wallerstein McConnell, New York, New York Medical College and Hospital for Women, New York, 1905, aged 73, died, June 12, of angina pectoris

Sidney Hamilton Streett, Baltimore, Baltimore Medical College, 1908, served in France during World War I, aged 59, died, June 29, of coronary thrombosis

Wilfrid Laurier McDougald, Westmount, Que., Canada, Queen's University Faculty of Medicine, Kingston, Ont., 1907, formerly senator, aged 60, died, June 19

Frank Ripley Halstead, Corpus Christi, Texas, Drake University College of Medicine Des Moines, Iowa, 1908, aged 76, died, June 15, of accidental drowning

Elmer Ellsworth Anderson, Fort Scott, Kan., Rush Medical College, Chicago 1884, aged 82, died recently of coronary heart disease and cerebral hemorrhage

Hugh Allan Stevenson, London, Ont., Canada, Western University Faculty of Medicine, London, 1894, Trinity Medical College Toronto, 1895, died recently

William Andrew M. McConkey, Edmonton, Alta., Canada, Manitoba Medical College, Winnipeg, 1906, aged 67, died recently in Coleman of heart disease

Sherman A. Askew, Peoria, Ill., National Medical University Chicago, 1907, aged 67, died, June 28, in St. Francis Hospital of congestive heart disease

Jesse Clifford Ross, Hawthorne, Calif., St. Louis College of Physicians and Surgeons, 1910, police surgeon, aged 57, died, June 7, of coronary occlusion

William M. Wilson, Tullahoma, Tenn., University of Tennessee Medical Department, Nashville, 1906, aged 69, died, June 10, of an infection of the arm

Kate Wilde-Glass, Venice, Calif., University of Southern California College of Medicine, Los Angeles, 1898, aged 74, died, June 22, of arteriosclerosis

Aaron Gable Miller, Wildwood, N. J., Jefferson Medical College of Philadelphia 1894, aged 83, died, June 10, in Sea Isle City of chronic myocarditis

William Thomas Hudson, Auburn, N. Y., Albany Medical College, 1899, aged 67, died, June 15, in the Jackson Memorial Hospital, Miami, Fla.

Joseph Henderson Estes, Little Rock, Ark., Medical Department of Tulane University of Louisiana, New Orleans, 1887, aged 79, died, June 15

William Irwin, Philadelphia, Jefferson Medical College of Philadelphia, 1897, formerly on the staff of St. Agnes Hospital, aged 86, died, June 7

Reuben Graham McCall, Sandpoint, Idaho, Hahnemann Medical College and Hospital, Chicago, 1916, aged 50, died recently of heart disease

Claude Bernard Hicks, Atlanta, Ga., University of Maryland School of Medicine, Baltimore, 1914, aged 56, died, June 24, of chronic nephritis

Raymond P. Harben, Dallas, Texas, University of Tennessee Medical Department, Nashville, 1895, aged 82, died, June 28, of myocarditis

Melvin Leonard Young, Ashland, Wis., University of the City of New York Medical Department, New York, 1885, aged 83, died, June 27

Horace Goodyear Baldwin, Tannersville, N. Y., Long Island College Hospital, Brooklyn, 1905, aged 64, died, June 9, of chronic myocarditis

Charles A. Service ☉ Philadelphia, Jefferson Medical College of Philadelphia, 1882, aged 82, died, June 22, in the Presbyterian Hospital

Gustav Adolph Herrmann, Alton, Ill., St. Louis Medical College, 1886, aged 78, died, June 1, in St. Anthony's Infirmary and Sanitarium

George H. Marvel, Lincoln, Neb., Lincoln Medical College of Coter University, 1905, aged 69, died, June 21, of cerebral hemorrhage

Sandford Loeb ☉ Portland, Ore., University of Oregon Medical School, Portland, 1902, aged 67, died, June 9, of cerebral hemorrhage

Jay C. Booher ☉ Falls Creek, Pa., Western Pennsylvania Medical College, Pittsburgh, 1892, aged 75, died, June 26, of coronary thrombosis

Alfred Alliegro, New York, Fordham University School of Medicine, New York, 1913, aged 52, died, June 18, of coronary thrombosis

Joseph W. Gregg, Madison, Ind., Central College of Physicians and Surgeons, Indianapolis, 1893, aged 73, died, June 5, of arteriosclerosis

Guy D. Doremus, Peoria, Ill., Curtis Physio-Medical Institute, Marion, Ind., 1894, aged 76, died, June 14, of carcinoma of the pancreas

George McD. Callaway, San Antonio, Texas, Medical College of Alabama, Mobile, 1889, aged 82, died, July 8, of arteriosclerosis

Otto Florea Fleener, Hammond, Ind., Medical College of Indiana, Indianapolis, 1898, aged 64, died, June 28, of carcinoma of the sigmoid

Mark Amberson Seavey, Sioux City, Iowa, Sioux City College of Medicine, 1908, aged 63, died, June 13, of pulmonary edema

Samuel Albert Brown, Canby, Ore., University of Michigan Homeopathic Medical School, Ann Arbor, 1880, aged 90, died, June 26

Nelson P. Grant, Woodstock, N. B., Canada, McGill University Faculty of Medicine, Montreal, Que., 1904, aged 69, died recently

Daniel Patrick Mahoney, St. John, N. B., Canada, College of Physicians and Surgeons, Baltimore, 1905, aged 67, died recently

William Eldridge Wright, Burlington, N. J., Hahnemann Medical College and Hospital of Philadelphia, 1890, aged 79, died recently

Ezra Rockwell Brooks, Atascadero, Calif., State University of Iowa College of Medicine, Iowa City, 1886, aged 81, died, June 21

George Henry Whitaker Whiteside, Omaha, Harvard Medical School, Boston, 1882, aged 87, died recently of second degree burns

James C. R. Gathings, La Feria, Texas, Memphis (Tenn.) Hospital Medical College, 1887, aged 79, died, June 14, in San Antonio

Simon Ravich, Los Angeles, Medico-Chirurgical College of Philadelphia, 1902, aged 68, died, June 3, of carcinoma of the stomach

William Henry Billings, Buffalo, University of Buffalo School of Medicine, 1906, aged 62, died, June 17, of pulmonary tuberculosis

William Wallace Parker ☉ Floris, Iowa, University Medical College of Kansas City, Mo., 1896, aged 69, died, June 27, of nephritis

Manning W. Manahan, Atlanta, Ga., Homeopathic Hospital College, Cleveland, 1882, aged 83, died, June 14, of myocarditis

Robert Otis Williams, Humboldt, Tenn., Eclectic Medical Institute, Cincinnati, 1900, aged 68, died, June 7, of arteriosclerosis

John L. M. Halstead, Sarver, Pa., Kentucky School of Medicine, Louisville, 1898, aged 72, died, July 19, of heart disease

Roger Walker Gray, Crane, Texas, Baylor University College of Medicine, Dallas, 1921, aged 44, was found dead, July 12

Edwin Ward Mackey, Tampa, Fla., Birmingham (Ala.) Medical College, 1909, aged 72, died, July 11, of diabetes mellitus

John St. Avit ☉ Cape Girardeau, Mo., St. Louis University School of Medicine, 1908, aged 78, died, June 8, of angina pectoris

Alfred Deyo, Derby, Ohio, Ohio Medical University, Columbus, 1893, aged 76, died, June 29, of cerebral hemorrhage

Abram Lincoln Weil ☉ Buffalo, University of Buffalo School of Medicine, 1898, aged 66, died July 5, of nephritis

George C. Fisher, Indianapolis, Kentucky School of Medicine, Louisville, 1883, aged 85, died June 5, of arteriosclerosis

Joseph Miller, Butler, Ind., Curtis Physio-Medical Institute, Marion, Ind., 1894, aged 82, died, June 1, of senility

William T. Steger, St. Louis, Missouri Medical College, St. Louis, 1891, aged 73, died, June 7, of heart disease

Thomas A. Langford, Hilham, Tenn. (licensed in Tennessee in 1889), aged 87, died, June 28

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines" or medical devices have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Arsenic Spring Water—That this constitutes a remedy or cure for diabetes high blood pressure constipation rheumatism malaria or liver stomach bladder or kidney disorders or is a tonic or an alternative or has no equal as a diuretic were unwarranted advertising claims which Robert Enrico trading as Arsenic Spring Water Company Hot Springs Ark. agreed to discontinue in his advertising according to a stipulation that he made with the Federal Trade Commission in January 1942. Enrico further agreed to cease representing that this water when taken internally will cleanse the skin have a significant laxative effect or be of value in treating skin diseases.

Baum's Ace Brand Corn Callous (?) and Bunion Salve—That this is an effective remedy or cure for corns calluses warts bunions or ingrown toenails is entirely safe for continued or repeated use or a 'new or scientific remedy' for disfigured feet due to these disorders were among the misrepresentations to be discontinued in the advertising according to a stipulation signed with the Federal Trade Commission in January 1942 by Joseph H. Baum, trading as Baum Laboratories Brooklyn. He further agreed to cease disparaging competitive products and to discontinue use of the word Laboratories as part of his trade name.

Carnation Cold Tablets—In October 1941 the Carnation Company of St. Louis signed a stipulation with the Federal Trade Commission agreeing to discontinue advertisements of this product which did not clearly reveal that the habitual or excessive use of the tablets may be dangerous or that persons suffering from conditions characterized by acute pain accompanied by nausea and vomiting should avoid taking them. It was further stipulated however that such advertisements need contain only a conspicuously printed caution that the product was to be used only as directed on the label and that the label must contain an appropriate caution against improper use of the tablets and also give adequate directions for employing them.

Father John's Medicine—A stipulation concerning this was signed with the Federal Trade Commission in January 1942 by Father John's Medicine Company Inc., Lowell Mass. formerly known as Carleton and Hovey Company. In this the concern agreed to cease representing the product as a remedy or effective treatment for colds or bronchial or throat irritations as a preparation rich in vitamins other than A and D and as one capable of increasing the appetite. Further the concern agreed to desist from advertising that the product will build resistance to bronchial and throat irritations or have any value in the preventive treatment thereof except to supply vitamin A in conditions in which it might be useful.

Goody's Headache Powders—These are put out by a concern known as Goody's Inc. Winston Salem N. C. In January 1942 this concern signed a stipulation with the Federal Trade Commission agreeing to discontinue advertisements which failed to reveal conspicuously that its headache powders should not be used in excess of the dosage recommended that frequent or long continued use may be dangerous causing skin eruptions mental derangement or dependence on a drug that use of this product may cause collapse and that it should not be taken by children. The concern was permitted however to limit its warning in the advertising to the statement Caution Use only as directed if and when the directions in the labeling contain a warning to the same effect. The concern further agreed to desist from advertising that the use of its product will remove the cause of symptoms indicated by headache neuralgia muscular aches and pains or that the powders have any value other than as a temporarily alleviating agent. In at least three cases on record the government has taken action against Goody's Inc. for violation of pure food and drug laws because their headache nostrum would be potentially injurious if used as directed on the label chiefly on account of the acetanilid that it contained.

Hexin—The Consolidated Royal Chemical Corporation trading as Consolidated Drug Trade Products Chicago stipulated with the Federal Trade Commission in September 1941 that it would discontinue the following misrepresentations that Hexin will relieve a cold or be of any benefit in treating the cold beyond giving temporary relief from the physical discomfort associated with that condition. The concern further agreed to discontinue any advertisements for Hexin which failed to reveal that frequent or continued use may be dangerous causing serious blood disturbances and that the product should not be taken in excess of the dosage recommended. The company was permitted however to employ the simple warning that its preparation should be used only as directed on the label if and when such label either contains a proper

caution or specifically directs attention to such a caution in the accompanying labeling. In Oct. 1941 Benson and Dahl Inc. Chicago which handles the Hexin advertising signed a similar stipulation with the Commission.

Hoyt's Compound—This is no longer to be represented as a competent remedy for kidney afflictions biliousness rheumatism stomach ailments indigestion or colds as a product to tone up the system restore health regulate the bowels and cleanse the blood stream or as a modern discovery made by the foremost authority in the United States. This was agreed in a stipulation signed with the Federal Trade Commission in March 1942 by Verne N. Seeley Herman P. Dovic and Fred D. Grantham trading as Hoyt Chemical Company Denver. These persons further stipulated that they would discontinue use of the word chemical in their trade name or the word chemists used in any manner to imply that they are chemists and that they will stop employing the word manufacturing or terms of similar meaning to give the impression that they manufacture the products that they sell.

Jolo Liverine Bee Bees Ru Ma Sol—These nostrums are put out by an A. J. Whiteside trading as Whiteside Company Wilmington Ohio. In a stipulation that he signed with the Federal Trade Commission in February 1942 he agreed to cease representing that any of his preparations is a new scientific natural or advanced medicine that Jolo ends many forms of health disorders has tonic action on the liver quiets quivering nerves and relieves the system of colds that Liverine enables the liver to function properly cleanses the blood stream or overcomes skin eruptions that Bee Bees is a genuine medicine or a new or remarkable discovery for weakened kidneys or irritated bladder and that Ru Ma Sol eliminates uric acid in the system goes to the very source of rheumatism or is a competent treatment for underlying conditions indicated by such symptoms as rheumatic pains swollen and stiffened fingers hands arms feet legs or joints neuritis sciatica lumbago and stomach pains.

Miracle Salve—This product was sold by one H. E. Studier trading as Rex H. E. Studier Lincoln Neb. In September 1941 Studier stipulated with the Federal Trade Commission that he would cease representing that Miracle Salve is a remedy or cure for or has any beneficial effect in the treatment of pains gout arthritis neuritis or other ailment.

Orangeine—This is advertised for use in relieving headache neuralgia and the discomforts arising from head colds. According to a stipulation made with the Federal Trade Commission in January 1942 Kemp Lane Inc. Le Roy N. Y. will discontinue any advertising which failed to reveal that Orangeine should not be used in excess of the recommended dosage that its frequent or continued use may be dangerous causing collapse or a dependence on a drug and that it should neither be taken by nor administered to children. The latter restriction however will be eased provided that the advertising shall contain a warning to use the product only as directed if and when the same caution appears in the labeling. A similar stipulation was given to the Commission around the same time by F. A. Hughes Company Inc. Rochester N. Y. which handles the advertising of Orangeine.

Physique Control Course Health O Flex System Courses and Health O Flexer—One Anthony Matyssek trading as Antone Matyssek Baltimore puts these out the first in the form of a booklet the second as a course of instruction and the third as an exercising device. In a stipulation which he signed with the Federal Trade Commission in February 1942 he agreed to discontinue the following advertising representations that the booklet reveals new strength secrets and will enable one to build up the body revitalize the spine heart lungs kidneys muscles and glands increase vitality create perfect circulation and correct rounded shoulders that the Health O Flex System Courses teach one how to make his weakest spots his strongest or increase his strength and endurance that the Health O Flexer constitutes an improved method of physical culture or gives strength health or attractiveness to the body that it reactivates the glands or ligaments invigorates the internal organs helps to eliminate surgical operations and the use of drugs and medicines prevents colds headaches backaches weakness or suffering and increases or reduces the weight as desired. Matyssek further agreed to cease representing that any specific results claimed for his products are guaranteed or that any offer he made was limited as to time when such was not a fact.

Stomavita Femovita Pulmotol and Renatone Pills—These were advertised by one Robert Salazar of Los Angeles trading as Los Angeles Pharmacal Company and as Hidalgo Pharmacal (Hidalgo Farmacia). In September 1941 the Federal Trade Commission accepted a stipulation from Salazar in which he agreed to discontinue the following misrepresentations that Stomavita is an effective treatment for dyspepsia acidity or stomach troubles generally or will permit the user to eat anything desired without ill effects that Femovita corrects female complaints or is an effective treatment for nervousness or muscular pain due to these that Pulmotol is a general tonic which aids in the growth of bones or teeth in children stimulates organic energy and conquers nervous debility and that Renatone Pills are a scientific discovery or have any beneficial action on the kidneys or that disorders such as rheumatism stomach trouble backaches lumbago or arthritis are cured by acid in the kidneys or are attributable solely to kidney ailments.

Tobacco Redeemer—This treatment promoted for the tobacco habit was said by the Federal Trade Commission to consist of a combination of drug preparations together with dietary information. In September 1941 J. E. Eggers trading as Newell Pharmacal Company St. Louis signed a stipulation with the Commission to discontinue the representation that his product is certain to cure the tobacco habit and also to cease representing by use of the word Pharmacal in his trade name or otherwise that he prepares the treatments or maintains a pharmacy or pharmaceutical facilities or a laboratory wherein tests have been made indicating their efficacy.

NEEDED SPINAL CORDS FROM FATAL OR OLD CASES OF POLIOMYELITIS

To the Editor—To those of your subscribers who are interested in poliomyelitis I wish to make an appeal.

What seems to be a promising line of attack is being seriously hampered by lack of material. Spinal cords from cases of the disease, acute and even more particularly chronic are needed. Therefore I beg that any one reading this letter will bear me in mind if the possibility of obtaining any such cord should come his way. Far from being a mere incidental, a single cord would be of major value. Accordingly the appeal is made especially to individual physicians and surgeons and to small hospitals which cannot be reached otherwise. Requirements are intact cords or intact upper or lower halves dura left on but slit up back for good fixation. Cord may be cut into equal thirds for convenience. Fixation preferably with 2 per cent glacial acetic acid in 95 per cent alcohol but may be with 10 per cent solution of formaldehyde in isotonic solution of sodium chloride solution use about a pint, please fix straight. I shall gladly pay ten dollars for technical assistance employed in removing a cord. If sections are required for local records I prefer to prepare them myself—if donor removes blocks for this purpose it greatly impairs the value of the material. Correspondence is cordially invited.

"FOUND A ONE DAY CURE FOR SYPHILIS"

To the Editor—As I have been quoted without permission, serious objection is taken to the recent article of Mr Paul de Kruif "Found A One Day Cure for Syphilis" (*Reader's Digest* September 1942).

First, this article is bound to dissatisfy a large number of conscientious patients suffering from syphilis. The course and the effects of the disease have been carefully explained to them by their physicians, and they have been satisfied and willing to carry out their treatment. "Everything was quiet along the Marne," and then they read or hear of this article and are greatly disturbed. Some think the physician does not know his business. They say "Here you promised to cure me and it is to take a year or more while Paul de Kruif writes I will be well after one day's treatment." Others query "What about this deadly arsenical treatment that you are giving me, while I might better be in a fever cabinet for a few hours, dozing away, smoking and listening to radio music?"

Second, it is most unfortunate that Mr de Kruif goes back to 1931 to dig up some old statistical data over a ten year period on arsenical reactions (Cole, H N and others *Toxic Effects Following Use of the Arsphenamines*, *THE JOURNAL*, Sept 26 1931, p 897) and then attempts to compare them with present day practice. Needless to say, reactions from present day treatment of syphilis with arsenicals (mapharsen) and with bismuth compounds are almost nil. Deaths are practically unheard of.

Third, one must remember that data on syphilis therapy are not gathered overnight, as Mr de Kruif would lead us to believe. Neither are they built up on 26 patients. It requires careful study of many patients and, too, observations of these same patients over a period of years. Serologic reactions over a period of a few months are worthless. The syphilologist who

draws conclusions from such serologic reactions alone is bound to fall into grave error.

Finally, even if Mr de Kruif felt it wise to write such an article, I wonder if the publishers of the *Reader's Digest* are blameless? In a way they are leaders in their field, if they confine themselves to their proper niche. Ordinarily articles intended to be medical in character are submitted not to lay editors but to critical medical editors. They are weighed from every angle and must pass the strictest inspection before being accepted. The evidence presented must be backed up by cold scientific data. This, of course has not been done with Mr de Kruif's article, for the *Reader's Digest* is not a medical publication and the publishers are not in a position to judge of the value of such an article.

The *Reader's Digest* has a wide field of usefulness. Its publishers are performing a service to the reading public. However medicine is not in their line and they are doing a great disservice when they accept such unscientific unsubstantiated articles as that of Mr de Kruif's.

HAROLD N COFF, M D, Cleveland

REPRINTS OF ARTICLES FOR RUSSIAN PHYSICIANS

To the Editor—I have just received a letter dated May 25 1942 from Prof Alexander R Luria the prominent Russian neuropsychologist. Professor Luria whose book in English "The Nature of Human Conflict" is well known to American readers and who was scheduled to visit this country to deliver the Salmon Memorial Lectures at the New York Academy of Medicine, is now in the province of Cheliabinsk in the Ural Mountains. He is directing a clinic for the rehabilitation of the brain injured in the war. He writes that he and his colleagues are very much in need of reprints from recent original American publications in the fields of brain pathology and abnormal psychology, particularly those dealing with reeducation and neurosurgery. He would like to receive such material of course as soon as possible.

The American Russian Committee for Medical Aid to the Union of Socialist Soviet Republics of which Prince Vladimir V Koudashoff is the chairman and Dr Michael Michailovsky is the treasurer has offered to transmit to Professor Luria literature sent to them and designated for him. Their address is 55 West Forty-Second Street New York City. It is also possible to mail directly to Prof A R Luria Neurosurgical Rehabilitative Clinic of Viem Kisegetch Sanatorium, Cheliabinsk Oblast, U S S R.

It is hoped that American medical men who have pertinent material will heed this call. It may furthermore be presumed that the needs of Professor Luria and his clinic are typical and that in general American scientists who have formerly corresponded with Russian colleagues should continue sending important reprints that in some way bear on war needs. Indeed, only three months ago I received from the Tbilisi Physiologic Institute a request for a reprint that is neither very important nor remotely related to war research. However the situation has doubtless changed since, and correspondents may do well to discriminate for the time being in what they send.

The U S Post Office accepts first class matter and printed material not exceeding 4 pounds 6 ounces for mailing to Russia, and wherever locations of institutes and universities have been changed as many have the Soviet authorities no doubt have the information for proper forwarding.

COMMON ERRORS IN THIOCYANATE MANAGEMENT OF HYPER- TENSION

To the Editor—In the article of Drs William O Russell and William C Stahl (*THE JOURNAL*, August 8, p 1177) reporting a case of fatal poisoning from potassium thiocyanate treatment of hypertension they write repeatedly of an "accepted therapeutic dose," "the usually prescribed amount of the drug," "the standard and accepted therapeutic dose," "the usually prescribed dose," "the usually prescribed amount," "the dose of thiocyanate usually prescribed and regarded as safe." The main thesis which Barker developed and has reiterated in all his publications on this subject is that there is no usual, standard or accepted therapeutic dose. Each case is an individual dosage problem depending largely on the age of the patient, the degree of vascular sclerosis, efficiency of renal function, the increment of blood thiocyanate concentration over a short period of time and the presence or absence of congestive heart failure. In examining the protocol of this case one finds that renal function was impaired as evidenced by albuminuria, urea clearance of 27 per cent and nonprotein nitrogen of 43 mg per hundred cubic centimeters. The liver edge was 2 cm below the costal margin, presumptive evidence of congestive cardiac failure. Since edema fluid also stores thiocyanate, reabsorption of this fluid into the blood stream during the course of returning cardiac compensation allows the contained thiocyanate an opportunity to become stored in the blood and tissues.

The entire purpose of blood thiocyanate determination during the first weeks of administration is to study the increment of the substance in the blood after short intervals of therapy with small doses (0.15 to 0.3 Gm) with a view of establishing a maintenance dosage. In the case reported the blood thiocyanate level rose from 45 to 152 mg per hundred cubic centimeters within seven days on a dose of 0.6 Gm of potassium thiocyanate in the presence of impaired renal function. While Barker's earliest papers reported nonfatal cases with blood thiocyanate levels up to 45 mg per hundred cubic centimeters it was clearly pointed out that such levels were toxic and the situation of those patients fraught with danger. The authors quote Barker to the effect that "significant toxicity begins to appear from 15 to 30 mg." It has been emphasized that 15 mg per hundred cubic centimeters of blood thiocyanate is the borderline between "safe" limits and the "severe" toxic manifestations (Wald, M H, Lindberg, H A, and Barker, M H. *The Toxic Manifestations of the Thiocyanates*, *THE JOURNAL*, March 25, 1939, p 1120). It is impossible, therefore, to agree with the authors that "the blood cyanates were always at supposedly nontoxic levels." The occurrence of such a rapid increase in blood thiocyanate and that to the critical level of 152 mg per hundred cubic centimeters constitutes a clear indication for temporary discontinuance of the drug. Resumption of medication at much reduced dosage should occur after the blood thiocyanate level has returned to from 8 to 12 mg per hundred cubic centimeters. A review of Garvin's case (*The Fatal Toxic Manifestations of the Thiocyanates*, *THE JOURNAL*, March 25, 1939, p 1125) clearly shows that substantially the same facts hold true. Reference should be made to the article of Kurtz, Shapiro and Mills (*The Results of Sulfocyanate Therapy of Hypertension*, *Am J M Sc* 202:378 [Sept.] 1941) for a discussion of this case.

I would expand on the conclusions of Drs Russell and Stahl by stating that any patient whose blood level exceeds 15 mg per hundred cubic centimeters is in danger of severe toxic manifestations which may be fatal. Moreover, I wish to reiterate that there is no usual or standard dosage for thiocyanate.

MAURICE H WALD, M D, Winnetka, Ill

MERCURIAL DIURETICS

To the Editor—To those of us who practiced medicine before the era of the mercurial diuretics, the articles which appeared in *THE JOURNAL*, July 25, pages 998 to 1011, seem almost sacrilegious. Then to cap the climax there is a case report in the August 8 issue in which a death is reported which cannot be attributed, even by the widest stretch of the imagination, to the injection of a mercurial diuretic one month before death.

Only in the paper of Drs Graff and Nadler is there even a hint as to the enormous number of injections that have been given in the course of the years. Still they were able to collect only twenty-six deaths in sixteen years and even in some of these it is questionable whether a mercurial diuretic played any part in the deaths. Mercurial diuretics are particularly indicated in cases in which sudden deaths are not uncommon and considering the fact that unquestionably millions of injections have been given, pure chance would give us considerably more deaths than those reported.

I myself have given or prescribed over a thousand intravenous injections of mercupurin without any untoward results, but there have been sudden deaths in these cases entirely unrelated to the injections. During May, June, July and part of August of this year I gave an elderly woman an injection of mercupurin every four or five days with excellent results. On August 11 an injection was indicated but, seeing the patient late, I decided to wait until the next day so that the patient's rest would not be disturbed. She received no injection but died very suddenly less than one hour later. Pure chance prevented a death immediately following a mercupurin injection.

Many more deaths, I am sure, result from the nonuse of mercurial diuretics in indicated cases than from their use. I fear the articles in question may influence the uncritical or inexperienced in the use of a most valuable drug—a drug which is truly remarkable when used in the proper cases, which by their very nature are inseparably associated with the possibility of sudden death.

MOSES SALZER, M D, Cincinnati

SILVER IN THE URINE

To the Editor—We have read the communication by Dr Joseph C Aub and Dr Lawrence T Fairhall (*THE JOURNAL*, Jan 24, 1942, p 319) in which the view is expressed that silver is not excreted in the urine. Since the comparatively non-strategic nature of silver has encouraged its industrial use during the emergency to replace some of its lowly but more essential metallic relatives, the subject of silver pharmacology may assume greater importance. We wish to call attention to our report of a case of obscure argyria with argyremia (*THE JOURNAL*, Nov 17, 1934, p 1521) in which it was demonstrated spectrographically that under certain conditions, at least significant amounts of silver may be eliminated from the body by excretion in the urine even three months after the cessation of silver ingestion. However, in an old case of well pigmented argyria in which there had been no abnormal silver absorption for at least ten years, and also in normal controls the metal could not be detected in the urine or was detected only as an extremely faint trace.

Maine March Report

The Maine Board of Registration of Medicine reports the written examination for medical licensure held at Portland, March 10 11, 1942. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Ten candidates were examined, 8 of whom passed and 2 failed. Four physicians were licensed to practice medicine by reciprocity and 3 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Harvard Medical School		(1939)	1
Tufts College Medical School		(1919) *	2

MEDICOLEGAL ABSTRACTS

Oklahoma Law Authorizing the Compulsory Sexual Sterilization of Habitual Criminals Unconstitutional—The Oklahoma Habitual Criminal Sterilization Act (Oklahoma Statutes Annotated, title 57, section 171-195) authorizes the attorney general to institute proceedings for the sexual sterilization of any person adjudged to be a habitual criminal, defined, in effect, to mean a person who has been convicted three or more times to final judgment of the commission of crimes amounting to felonies involving moral turpitude and on the basis of the last conviction sentenced to imprisonment in an Oklahoma penal institution. The act provides, however, that "offenses arising out of the violation of the prohibitory laws, revenue acts, embezzlement, or political offenses, shall not come or be considered within the terms of" the act. Questions of fact involved in a proceeding such as that referred to may, on the demand of either party, be tried by jury and, if the court or jury, as the case may be, finds the defendant to be a habitual criminal and that he or she may be rendered sterile without detriment to his or her general health, the court may, subject to an appeal to the Supreme Court of Oklahoma, order sterilization. Such a proceeding was instituted against the defendant Skinner, who was confined in a state penitentiary and had been convicted once of stealing chickens and twice of robbery with firearms, the last conviction being had in 1934, a year before the enactment of the act. A jury found that the defendant was a habitual criminal within the meaning of the act and that his general health would not be impaired by a sterilization operation. Accordingly, the trial court ordered him to be made sexually sterile, and the defendant appealed to the Supreme Court of Oklahoma, which affirmed the judgment of the lower court (*Skinner v State of Oklahoma ex rel Williamson*, 115 P (2d) 123, J A M A 117 1463 [Oct 25] 1941). The defendant then brought certiorari to the Supreme Court of the United States.

The defendant questioned the validity of the act under which he had been ordered to be made sexually sterile on a number of constitutional grounds which the Supreme Court did not find necessary to pass on, since, in the opinion of the court, the act in question was clearly violative of the equal protection of the law clause of the federal constitution because of the inequality of treatment permitted by the act. The inequality of treatment is made possible, said the court, by the provision of the act that "offenses arising out of the violation of the prohibitory laws, revenue acts, embezzlement, or political offenses should not be considered within its terms. In Oklahoma grand larceny is a felony and larceny is grand larceny when the property taken exceeds \$20 in value. Embezzlement which is specifically excluded from the terms of the habitual criminal sterilization act, is punishable in the manner prescribed for feloniously

stealing property of the value of that embezzled. Hence a person who embezzles property worth more than \$20 is guilty of a felony. A clerk who appropriates more than \$20 from his employer's till and a stranger who steals the same amount are thus both guilty of felonies. If the stranger repeats his act and is convicted three times he may be sterilized. But the clerk is not subject to the pains and penalties of the sterilization act no matter how large his embezzlements nor how frequent his convictions. A person who enters a chicken coop and steals chickens commits a felony and he may be sterilized if he is thrice convicted. If however, he is a bailee of the property and fraudulently appropriates it, he is an embezzler and hence not subject to sterilization no matter how habitual his proclivities for embezzlement are and no matter how often his conviction. Thus the nature of the two crimes is intrinsically the same and they are punishable in the same manner. Furthermore, the line between them—that is, the line between a larceny and an embezzlement—follows close, technical distinctions. There may be larceny by fraud rather than embezzlement even when the owner of the personal property delivers it to the defendant, if the latter has at that time a fraudulent intention to make use of the possession as a means of converting such property to his own use and does so convert it. If however, the fraudulent intent occurs after the delivery of the property and the defendant then converts the property he is guilty of embezzlement. Whether a particular act is larceny by fraud or embezzlement thus turns not on the intrinsic quality of the act but on when the felonious intent arose—a question for the jury under appropriate instructions.

This court, continued the court has held that the equal protection clause of the constitution does not prevent the legislature from recognizing the "degrees of evil" and that the constitution does not require things which are different in fact or opinion to be treated in law as though they were the same. Thus if we had here only a question as to a state's classification of crime, such as embezzlement or larceny, no substantial federal question would be raised, for a state is not constrained in the exercise of its police power to ignore experience which marks a class of offenders or a family of offenses for special treatment. Nor is a state prevented by the equal protection clause from confining its restrictions to those classes of cases in which the need is deemed to be clearest. As was stated by this court in *Buck v Bell* 274 U S 200, 47 S Ct 584 in which the validity of the Virginia compulsory sterilization law was upheld.

The law does all that is needed when it does all that it can. It indicates a policy, applies it to all within the lines and seeks to bring within the lines all similarly situated so far and so fast as its means allow.

But, continued the Supreme Court, the Oklahoma habitual criminal sterilization act, here under consideration, runs afoul of the equal protection clause though we give Oklahoma that large deference which the rule announced requires. We are dealing here with legislation which involves one of the basic civil rights of man. Marriage and procreation are fundamental to the very existence and survival of the race. The power to sterilize, if exercised may have subtle far reaching and devastating effects. In evil or reckless hands it can cause races or types which are inimical to the dominant group to wither and disappear. There is no redemption for the individual whom the law touches. Any experiment which the state conducts is to his irreparable injury. He is forever deprived of a basic liberty. We advert to these matters merely in emphasis of our view that strict scrutiny of the classification which a state makes in a sterilization law is essential. Less unwittingly or otherwise invidious discriminations are made against groups or types of individuals in violation of the constitutional guaranty of just and equal laws. The guaranty of equal protection of the laws is a pledge of the protection of equal laws. When the law lays an unequal hand on those who have committed intrinsically the same quality of offense and sterilizes one and not the other, it has made as invidious a discrimination as if it had selected a particular race or nationality for oppressive treatment. Sterilization of those who have thrice committed grand larceny with immunity for those who are embezzlers is a clear pointed

Maine March Report

The Maine Board of Registration of Medicine reports the written examination for medical licensure held at Portland, March 10 11, 1942. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Ten candidates were examined, 8 of whom passed and 2 failed. Four physicians were licensed to practice medicine by reciprocity and 3 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad	Number Passed
Harvard Medical School	(1939)		1
Tufts College Medical School	(1919) *	(1940)	2
New York University College of Medicine	(1939)		1
Medizinische Fakultät der Universität Wien	(1935)	(1936)	2
Regia Università di Napoli Facoltà di Medicina e Chirurgia	(1938)		1
Universität Bern Medizinische Fakultät	(1937)		1

sterling property of the value of that embezzled. Hence, a person who embezzles property worth more than \$20 is guilty of a felony. A clerk who appropriates more than \$20 from his employer's till and a stranger who steals the same amount are thus both guilty of felonies. If the stranger repeats his act and is convicted three times, he may be sterilized. But the clerk is not subject to the pains and penalties of the sterilization act no matter how large his embezzlements nor how frequent his convictions. A person who enters a chicken coop and steals chickens commits a felony, and he may be sterilized if he is three times convicted. If, however, he is a bailee of the property and fraudulently appropriates it, he is an embezzler and hence not subject to sterilization no matter how habitual his proclivities for embezzlement are and no matter how often his conviction. Thus the nature of the two crimes is intrinsically the same and they are punishable in the same manner. Furthermore, the line between them—that is, the line between a larceny and an embezzlement—follows close, technical distinctions. There may be larceny by fraud rather than embezzlement even when the owner of the personal property delivers it to the defendant, if the latter has at that time a fraudulent intention to make use of the possession as a means of converting such property to his own use and does so convert it. If, however, the fraudulent intent occurs after the delivery of the property and the defendant then converts the property, he is guilty of embezzlement. Whether a particular act is larceny by fraud or embezzlement thus turns not on the intrinsic quality of the act but on when the felonious intent arose—a question for the jury under appropriate instructions.

This court, continued the court, has held that the equal protection clause of the constitution does not prevent the legislature from recognizing the 'degrees of evil' and that the constitution does not require things which are different in fact or opinion to be treated in law as though they were the same. Thus, if we had here only a question as to a state's classification of crime, such as embezzlement or larceny, no substantial federal question would be raised, for a state is not constrained in the exercise of its police power to ignore experience which marks a class of offenders or a family of offenses for special treatment. Nor is a state prevented by the equal protection clause from confining its restrictions to those classes of cases in which the need is deemed to be clearest. As was stated by this court in *Buel v. Bell*, 274 U. S. 200, 47 S. Ct. 584 in which the validity of the Virginia compulsory sterilization law was upheld.

The law does all that is needed when it does all that it can indicate a policy applies it to all within the lines and seeks to bring within the lines all similarly situated so far and so fast as its means allow.

But, continued the Supreme Court, the Oklahoma habitual criminal sterilization act, here under consideration, runs afoul of the equal protection clause though we give Oklahoma that large deference which the rule announced requires. We are dealing here with legislation which involves one of the basic civil rights of man. Marriage and procreation are fundamental to the very existence and survival of the race. The power to sterilize, if exercised, may have subtle, far reaching and devastating effects. In evil or reckless hands it can cause races or types which are inimical to the dominant group to wither and disappear. There is no redemption for the individual whom the law touches. Any experiment which the state conducts is to his irreparable injury. He is forever deprived of a basic liberty. We advert to these matters merely in emphasis of our view that strict scrutiny of the classification which a state makes in a sterilization law is essential, less unwittingly or otherwise invidious discriminations are made against groups or types of individuals in violation of the constitutional guaranty of just and equal laws. The guaranty of equal protection of the laws is a pledge of the protection of equal laws. When the law lays an unequal hand on those who have committed intrinsically the same quality of offense and sterilizes one and not the other, it has made as invidious a discrimination as if it had selected a particular race or nationality for oppressive treatment. Sterilization of those who have thrice committed grand larceny with immunity for those who are embezzlers is a clear, pointed,

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Oklahoma Law Authorizing the Compulsory Sexual Sterilization of Habitual Criminals Unconstitutional—The Oklahoma Habitual Criminal Sterilization Act (Oklahoma Statutes Annotated, title 57, section 171-195) authorizes the attorney general to institute proceedings for the sexual sterilization of any person adjudged to be a habitual criminal, defined, in effect, to mean a person who has been convicted three or more times to final judgment of the commission of crimes amounting to felonies involving moral turpitude and on the basis of the first conviction sentenced to imprisonment in an Oklahoma penal institution. The act provides, however, that 'offenses arising out of the violation of the prohibitory laws, revenue acts, embezzlement or political offenses, shall not come or be considered within the terms of' the act. Questions of fact involved in a proceeding such as that referred to may, on the demand of either party, be tried by jury and, if the court or jury, as the case may be, finds the defendant to be a habitual criminal and that he or she may be rendered sterile without detriment to his or her general health, the court may, subject to an appeal to the Supreme Court of Oklahoma, order sterilization. Such a proceeding was instituted against the defendant Skinner, who was confined in a state penitentiary and had been convicted once of sterling chickens and twice of robbery with firearms the last conviction being had in 1934, a year before the enactment of the act. A jury found that the defendant was a habitual criminal within the meaning of the act and that his general health would not be impaired by a sterilization operation. Accordingly, the trial court ordered him to be made sexually sterile, and the defendant appealed to the Supreme Court of Oklahoma, which affirmed the judgment of the lower court (*Skinner v. State of Oklahoma ex rel. Williamson*, 115 P. (2d) 123 J. A. M. A. 117 1463 [Oct. 25] 1941). The defendant then brought certiorari to the Supreme Court of the United States.

The defendant questioned the validity of the act under which he had been ordered to be made sexually sterile on a number of constitutional grounds which the Supreme Court did not find necessary to pass on, since, in the opinion of the court, the act in question was clearly violative of the equal protection of the law clause of the federal constitution because of the inequality of treatment permitted by the act. The inequality of treatment is made possible, said the court, by the provision of the act that "offenses arising out of the violation of the prohibitory laws, revenue acts, embezzlement, or political offenses" should not be considered within its terms. In Oklahoma grand larceny is a felony and larceny is grand larceny when the property taken exceeds \$20 in value. Embezzlement, which is specifically excluded from the terms of the habitual criminal sterilization act, is punishable in the manner prescribed for feloniously

unmistakable discrimination Oklahoma makes no attempt to say that he who commits larceny by trespass or trick or fraud has biologically inheritable traits which he who commits embezzlement lacks Oklahoma's line between larceny by fraud and embezzlement is determined, as we have noted, with reference to the time when the fraudulent intent to convert the property to the taker's own use arises We have not the slightest basis for inferring that that line has any significance in eugenics nor that the inheritability of criminal traits follows the neat legal distinctions which the law has marked between those two offenses In terms of fines and imprisonment the crimes of larceny and embezzlement rate the same under the Oklahoma laws Only when it comes to sterilization are the pains and penalties of the law different The equal protection clause would indeed be a formula of empty words if such conspicuously artificial lines could be drawn In *Buck v Bell* supra, the Virginia statute was upheld though it applied only to feeble minded persons confined in state institutions But it was pointed out that "so far as the operations enable those who otherwise must be kept confined to be returned to the world and thus open the asylum to others, the equality aimed at will be more nearly reached" Here there is no such saving feature Embezzlers are forever free Those who steal or take in other ways are not If such a classification were permitted, the technical common law concept of some crimes based on distinctions which are very largely dependent on history for explanation could readily become a rule of human genetics The Supreme Court accordingly reversed the judgment of the trial court ordering the sexual sterilization of the defendant

In a special concurring opinion, Mr Chief Justice Stone argued that the act was constitutionally offensive not because of its failure to afford equal protection but rather because the act by its wholesale condemnation of a class to such an invasion of personal liberty as sterilization without opportunity to any individual to show that his is not the type of case which would justify resort to sterilization does not satisfy the demands of due process The act, it is true, does provide a hearing for an accused, but the hearing contemplated is a hearing not on the question as to whether or not the criminal defects, if any, observable in him are transmissible to potential offspring but solely on whether or not the accused is a habitual criminal, as defined in the act, and whether or not the accused may be rendered sexually sterile without detriment to his general health Undoubtedly, said the Chief Justice, a state may, after appropriate inquiry, constitutionally interfere with the personal liberty of the individual to prevent the transmission by inheritance of his socially injurious tendencies But until now the Supreme Court has not been called on to say that a state may do so without giving the defendant a hearing and opportunity to challenge the existence as to him of the only facts which could justify so drastic a measure Science has found, and the law has recognized, that there are certain types of mental deficiency associated with delinquency which are inheritable But the state does not contend—nor can there be any pretense—that either common knowledge or experience, or scientific investigation has given assurance that the criminal tendencies of any class of habitual offenders are universally or even generally inheritable In such circumstances, inquiry whether such is the fact in the case of any particular individual cannot rightly be dispensed with Whether the procedure by which a statute carries its mandate into execution satisfies due process is a matter of judicial cognizance A law which condemns without hearing all the individuals of a class to so harsh a measure as the present one because some or even many merit condemnation is lacking in the first principles of due process And so, while the state may protect itself from the demonstrably inheritable tendencies of the individual which are injurious to society, the most elementary notions of due process would seem to require it to take appropriate steps to safeguard the liberty of the individual by affording him, before he is condemned to an irreparable injury in his person, some opportunity to show that he is without such inheritable tendencies—*Skinner v State of Oklahoma ex rel Williamson, Atty Gen of Oklahoma, 62 S Ct 1110 (1942)*

Libel and Slander Report by Examining Physician to Examinee's Employer Not Actionable—The plaintiff, apparently to retain her employment with a certain federal agency, submitted herself to examination by the physician defendant to determine her fitness for the work in which she was employed As required, he reported the results of his examination to the regional head of the federal agency As to just what that report contained, the decision here abstracted does not make clear, but seemingly, at least in the plaintiff's view, it cast a reflection on her mentality, and she subsequently brought suit for libel, based on the report, against the physician The trial court directed a verdict in favor of the physician and the plaintiff appealed to the Supreme Court of Florida, division A

The Supreme Court held that the physician in reporting the results of his examination of the plaintiff to her superior in the federal agency had not committed any actionable libel In so holding the court quoted at length from 33 American Jurisprudence 168-170 and 36 C J 1242, which would seem to be authority for the statements following The report of the physician with respect to his examination to determine fitness for employment of an employee is qualifiedly privileged if made in good faith and without actual malice and if made to a person having a legitimate interest in the subject matter of the communication or report The report in this case was made by the physician in good faith and without actual malice, and since it was made to her superior in the federal agency it was made to one having a legitimate interest in the subject matter of the report Under such circumstances, even if the report was erroneous, the physician would have a complete defense in an action for libel based on the report Aside from the question of qualified privilege, however, the court did not think that the report complained of, when properly and reasonably construed, constituted the reflection on the plaintiff's mentality which the plaintiff attributed to it In fact, as the court construed the report, it constituted no reflection whatever on her character or mental status

For the reasons stated, the judgment in favor of the physician was affirmed—*Leonard v Wilson, 8 So (2d) 12 (Fla, 1942)*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamp to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Cold Pressor Test—Observations on cold pressor tests in 350 persons with normal blood pressure are presented by Feldt and Wenstrand. The data obtained by them with regard to the family history do not agree with those of Hines. Twenty-nine and seven tenths per cent were hyperreactors to the test, and 27.4 per cent had a family history of hypertensive cardiovascular disease. There was no relationship between the response to the cold pressor test and the family history.

Therapeutic Pericarditis—Two cases of pericarditis produced by the injection of 18 cc of a 5 per cent solution of sodium morrhuate and 2 cc of iodochlor directly into the pericardial sac of man without exposing the heart are reported. Rakov caused the pericarditis with the hope of benefiting the chronic coronary insufficiency. The result was apparently beneficial. The clinical manifestations of the pericarditis were fever, leukocytosis, and pericardial friction rub and although the alterations in the ST segment usually observed in acute pericarditis were absent, later electrocardiograms showed T wave inversions suggestive of a healing stage. These T wave alterations may be accepted as evidence that the epicardial barrier between intercoronary and extracoronary circulation was removed. The clinical improvement observed might be caused by the rapid opening of intercoronary communications. Further observation and microscopic study of the patients is necessary.

Mixed Infections in Bacterial Endocarditis—From the blood of 6 patients with bacterial endocarditis Orgun and Peston repeatedly cultured two or more distinct species of bacteria. In 2 the organisms were *Streptococcus viridans* and *Streptococcus hemolyticus*, in 1 *Strep viridans* and *Strep hemolyticus* growing in symbiosis with an unidentified gram negative rod, in 1 *Strep viridans* and *Hemophilus parainfluenzae*, in 1 *Streptococcus fecalis* and *Strep hemolyticus* and in 1 *Neisseria gonorrhoea* and a nonhemolytic anaerobic streptococcus. In the first 5 the organisms were grown on routine laboratory mediums, while in the sixth gonorrhea organisms were suspected and appropriate mediums were employed. There was little in the history, physical and laboratory data and clinical course of the patients to suggest mixed infection. Therefore the necessity for careful bacteriologic study as the only means of identification is obvious. Recognition of a mixed infection in bacterial endocarditis is of fundamental importance in therapy since all organisms must be eradicated from the blood and the vegetations if a cure is to be accomplished.

Sulfaguanidine in Nonspecific Ulcerative Colitis

Kirsner and his co workers discuss their experience with sulfaguanidine in treating 20 patients. 12 had nonspecific ulcerative colitis, 2 also had venereal lymphogranuloma of the rectum, 2 also had bacillary dysentery and 4 had miscellaneous intestinal infections. The sulfaguanidine was used in addition to the usual therapy employed for each disorder. The amount of the drug used and the duration of treatment varied according to the individual. It appears from the study that sulfaguanidine is of no value in the management of nonspecific ulcerative colitis. However, since it is possible that related compounds may prove beneficial their continued trial in nonspecific ulcerative colitis seems justified. The drug was ineffective in the treatment of 1 patient with venereal lymphogranuloma and of definite though not curative value in the other. The clinical improvement was associated with a definite decrease in the bacterial count of the feces. However sulfaguanidine had no advantage over other sulfonamides in the treatment of this condition. Chemotherapy was of slight and temporary value in the treatment of 2 patients with a *Shigella paradysenteriae* Flexner infection but was of no benefit in 1 with a paratyphoid B infection and in another with an infection of the biliary tract. Sulfaguanidine in daily doses of 10 to 15 Gm usually decreased the bacterial count of the feces and transformed the flora from one predominantly coliform to one composed almost entirely of gram positive organisms.

Stricture of Rectum Due to Venereal Lymphogranuloma

Levy and his associates treated 118 patients suffering from rectal stricture due to venereal lymphogranuloma with sodium sulfamyl sulfanilate. The initial dose was 5 Gm and thereafter 0.5 Gm three times a day. Many of the patients had previously received several forms of chemotherapy. After three to four weeks there was more striking improvement with sodium sulfamyl sulfanilate than with any previous treatment. That anemia diminished was evidenced by an increase in erythrocytes and hemoglobin gain in weight, diminished edema, regeneration of the rectal mucosa and relief of symptoms. Since sodium sulfamyl sulfanilate was used dilation was necessary for only 4 patients, 5 per cent as against the previous 75 per cent. None of the patients treated with sodium sulfamyl sulfanilate required colostomy. However, the patients

continued to have a positive Frei test. Many patients had complete disappearance of symptoms. When discharge persisted, sulfathiazole either alone or with sodium sulfanilyl sulfanilate caused it to disappear in most cases. The persistent discharge was probably due to secondary bacterial infection which required sulfathiazole.

"Safe" Universal Donor Blood in Exsanguinating Hemorrhage—As a precaution in 20 group AB patients Wiener and Pennell neutralized the isoagglutinins in the blood from group O donors by adding a solution of purified A and B substances as recommended by Witelsky, Klendshoj and Swanson. Grouping tests of a patient's blood after transfusions of neutralized group O and group AB blood showed it to consist of a mixture of approximately equal parts of group O and group AB blood, demonstrating that the two bloods remained in the patient's circulation. The fact that this patient's hemoglobin after a subtotal gastrectomy was only 88 per cent while on admission it had been 100 per cent, and this despite the fact that more than 5 liters (5,000 cc) of blood had been transfused, indicates that he lost at least as much blood as he received. In fact the patient must have been almost completely exsanguinated and there can be no doubt that without the transfusions he could not have survived the operative procedure. The transfusion of plasma alone would undoubtedly have been inadequate to maintain life. In smaller hemorrhages the loss of erythrocytes is not serious, and satisfactory results can be obtained by merely restoring the blood volume with the transfusion of plasma. In emergencies when little or no whole blood is available, plasma is of great value and it is far superior to dextrose and saline infusions, but, if the hemorrhage continues, at least one transfusion of whole blood should be given for every two or three transfusions of plasma. Transfusion of outdated bank blood would result in only temporary benefit.

Serum Cholesterol and Atherosclerosis in Chronic Glomerulonephritis—Steiner and Domanski studied the protocols of 54 patients from 1 to 39 years of age who died of renal disease. Gross atherosclerosis of the aorta was revealed in 52 and coronary atherosclerosis in 38. Coronary atherosclerosis was not found if at least mild aortic lesions were not present. Gross to moderate aortic atherosclerosis was present

in 7 of the 8 who were between 1 and 9 years of age. No coronary lesions were observed in this group. In the next three decades, coronary atherosclerosis was almost as prevalent as aortic atherosclerosis. The lesions were more widespread and frequently of greater magnitude in persons in the third and fourth decades. Study of 54 random patients in the same age group not dying of renal disease revealed gross aortic atherosclerosis in 19 and gross coronary atherosclerosis in 11. The difference between the two groups is more striking in the first two decades, since atherosclerosis was present in 14 of 15 of the first group in contrast to 1 of 15 in the control group. Also the degree of lipid infiltration in this group was less pronounced than in patients dying of renal disease. Serum cholesterol values in 30 of the 54 patients dying of renal disease exceeded 300 mg per hundred cubic centimeters in 17. In 12 of the 17 the value exceeded 400 mg. Serum cholesterol studies carried out over two years in 18 patients with chronic glomerulonephritis revealed that hypercholesterolemia was present in all on one or more occasions. In 17 the value exceeded 400 mg and in 10 it exceeded 600 mg.

Corpus Luteum Cyst and Ectopic Pregnancy—Israel emphasizes the remarkable resemblance presented by a corpus luteum cyst and extrauterine pregnancy and draws attention to the fact that the mimicry may be heightened by a positive Friedman test and the finding of well developed decidua like endometrial changes. The histories of 5 patients, each of whom had a corpus luteum cyst which was diagnosed preoperatively as an ectopic pregnancy, are cited. The histories illustrate the reasons for the diagnostic errors, including endometrial changes and a falsely positive biologic pregnancy test in 2 instances. It is suggested that if patients with a suspected adnexal tumor and a history suggesting ectopic gestation were not operated on for a few days but carefully observed, an occasional needless abdominal operation would be avoided.

Sulfonamide Toxicity in Newborn Infant—A heretofore unreported sulfonamide toxicity, toxicity in the newborn whose mothers were treated with sulfanilamide during pregnancy, in 2 cases is reported by Ginzler and Chesner, who caution against the indiscriminate use of the sulfonamides, specifically, during pregnancy. One of the infants died of acute yellow atrophy of the liver caused by the sulfanilamide transmitted from the mother through the placenta. The infant who recovered had acute hemolytic anemia, in this infant the same mechanism seems probable. Because of the clinical and hematologic features the cases were apparently erroneously diagnosed as erythroblastosis fetalis.

Exercises in Postoperative Thrombophlebitis—Krebs determined the incidence of postoperative thrombophlebitis among 209 patients given bicycling exercise postoperatively and 305 who were not. Of the total 517 patients, 376 had major and 141 had minor operations. None of the patients who exercised from the first postoperative day until discharge had thrombophlebitis. One of these patients, who discontinued the exercises after six days because of a postoperative infection, had the disorder. If the exercises had been continued, perhaps the phlebitis would not have developed. In contrast, thrombophlebitis developed in 5 of the 308 patients operated on during the same period of time but not having the advantage of bicycle exercises. The regimen does not unduly burden the nursing staff of any modern hospital. On the first day after operation the nurse instructs the patient in the use of the apparatus and the desired speed of motion. On subsequent days no further instruction is needed. To offset the lack of exercises on the day of operation, the foot of the bed should be elevated to aid in speeding the venous return flow from the legs.

Vitamin C Deficiency and Dental Conditions in Mental Patients—Barahal and Priestman made quantitative determinations of the vitamin C levels of mental patients and found that they were considerably lower than in normal control subjects. The low levels were at least partially traced to the low

vitamin C allowance in most institutional diets, but undoubtedly the unusual food habits of mental patients, depending on their delusions regarding food, played a part. There was a definite correlation between the frequency of dental and gingival conditions in mental patients and their low levels of vitamin C. There were no significant differences in the various diagnostic groups (old residents and newly admitted patients whose diets were or were not supplemented by "outside" food) except that patients with alcoholic psychosis had the lowest levels. Hospital diets should be supplemented by an adequate supply of vitamin C.

Paget's Disease of Nipple—The records of 20 cases of Paget's disease of the nipple treated over approximately twenty-three years are reviewed by West and Nickel. The diagnosis was based on the presence of an eczema or excoriation of the nipple which, on histologic section, showed epithelial hypertrophy, subepithelial round cell infiltration and Paget's cells. The cases were readily divided into two clinical groups. 1. All but 2 of the 13 patients in this group were more than 50 years of age and the chief complaint of each was eczema of the nipple, usually of long duration. In only 3 was the lesion of the nipple present for less than one year. Section of the breasts, after removal, revealed a definite tumor in 8, 3 of whom had axillary metastasis. Of the 3 patients with axillary metastasis, 1 died six months and 1 four years after operation, 1, operated on only a year ago, is alive and well without evidence of recurrence. The other 10 patients are alive and well, 2 for more than fifteen years, 1 for ten years, 1 for nine years, 3 for three years, and 3 were operated on within the last year. This group of 13 cases emphasizes the close relationship between chronic lesions of the nipple and carcinoma of the breast and suggests that carcinoma of nipple origin is slow to metastasize and therefore forms a favorable group for proper treatment. All lesions of the nipple which do not quickly respond to simple treatment should be subjected to a biopsy and if the diagnosis is Paget's disease, a radical mastectomy should be performed. 2. The 7 patients in this group were aware of a tumor of the breast at the time they sought medical advice, and only 2 complained of an associated eczema of the nipple. The lesions of the nipple were so inconspicuous that the clinical diagnosis of Paget's disease was not made in any of them. Microscopic study of the nipples revealed changes similar to those of the first group. Four of the patients are known to have died of their carcinoma within three years of operation, 1 has been alive for one year but has a local recurrence, and the result in 2 is not known.

Mixed Tumors of Parotid Gland—As experimental disturbance of tissue environment of the embryo has caused structural malformation, it is possible that some such disturbances may lead to the development of mixed tumors of the parotid gland. The time during embryonic life that such a disturbance occurs, as suggested by Li and Yang, would account for the degree of differentiation which the tissues show. Those occurring earlier in life have the greater potentialities of differentiation. This interrelationship of tissues Hemplemann and Womack point out has been almost completely ignored in the case of mixed tumors of the salivary gland type but has been used to explain the development of teratomas. This utilization of the "organizer" conception regards the tumors as a result of primary epithelial maldevelopment with mesodermal differentiation secondary to this epithelial disturbance. The application of this theory to mixed tumors of the salivary glands has not yet been subjected to experimental proof but it seems to the authors to be the most rational and is thoroughly in keeping with present day embryologic tenets.

Adenolymphoma of Parotid Gland—Plaut discusses the clinical aspects of adenolymphoma of the parotid gland as revealed in 48 previously reported cases and 16 as yet unreported instances. The tumor occurs at all ages, but predominantly in the fifth sixth and seventh decades. Its life history is that of a slow growing and relatively asymptomatic tumor. It occurred five times as often in men as in women. Surgical excision was the treatment of choice. Since the capsule is not always complete the tumor should be meticulously dissected out rather than enucleated. When completely excised it rarely recurs. Histologically it is benign. Added to the 64 cases are 3 others which although their microscopic picture is slightly different undoubtedly belong to the same group of neoplasms. Clinically they behave in an identical manner. Like the usual adenolymphoma they contain a matrix of lymphoid tissue diffuse lymphocytic infiltration aggregates resembling germinal centers large cells which resemble epithelioid cells small cysts lined with low cylindric cells with vesicular nuclei small cuboidal irregularly spaced cells and other single and strands of epithelial cells. Neisse who studied the parotid ducts and acini within the surrounding lymph nodes in fetuses and newborn infants felt that the parotid tissue became included in the lymph nodes as a result of the growth and development of the nodes from small patches of lymphocytes which had previously surrounded the parotid tissue. He found undeveloped parotid structures directly adjacent to lymphocytic tissue in 9 cm fetuses and lying within the nodes themselves in fetuses measuring 12 cm and larger. The observations of Bunting and Tennant on 2 premature and 5 full term, stillborn infants concurred. In most instances these glandular structures were situated in the hilar regions of the nodes. From the similarity of the structure of the 3 tumors reported by the authors to that of this common finding in newborn infants, it seems probable to them that such tumors have arisen from the subsequent growth of such parotid tubules and acini as have been included within lymph nodes.

Pheochromocytoma of Adrenal—Kirshbaum and Balkin report 3 cases of epinephrine producing pheochromocytoma of the adrenal from a series of 14,437 consecutive necropsies performed at the Cook County Hospital from 1929 to March 1941 inclusive. Operations were performed in 18 of the 116 cases reported to date, and there was a definite permanent drop in blood pressure in those in which survival occurred. The presence of an increased amount of epinephrine in the blood was demonstrated during an attack of 1 of the 13 in which biologic assays were performed. The epinephrine content of the tumors examined varied from 1 to 40 mg per gram of tumor tissue. One of the authors specimens contained 415 mg of epinephrine per gram of tissue. Usually pheochromocytoma is diagnosed in necropsy material, and it is only since 1929, following the report of Rabin that clinicians have made the diagnosis during life. The clinical diagnosis is usually made on the basis of paroxysmal hypertension accompanied by glycosuria, vasomotor pallor followed by flushing, headache, nausea, vomiting, dyspnea, a feeling of suffocation, pulmonary edema and great susceptibility to surgical shock. There have been patients with paroxysmal hypertension who have been operated on with

the diagnosis of pheochromocytoma of the adrenal but in whom no tumor was found. Recently Kirshba m saw a woman patient of 38 who was operated on for a suspected pheochromocytoma, but examination of the surgically removed tumor revealed a cyst of the adrenal which, when assayed, contained no epinephrine. Removal of the tumor has produced no fall in blood pressure.

Pheochromocytoma with Hypermetabolism—Two cases of pheochromocytoma of the adrenal gland with hypermetabolism are presented by McCullagh and Engel, who state that in 1 a severe diabetes mellitus existed, together with an extreme polyuria, amounting to as much as 16,800 cc daily. The correct diagnosis was made preoperatively in 1. This was aided by clinical data but without the aid of demonstrating the tumor. In this case operative removal of the tumor has led to a complete cure. Following operation this patient presented an unusual complaint of intolerance to cold. If a cold breeze struck her she would shiver perceptibly, and on one occasion the shivering continued for most of an hour. This has gradually improved until eight months postoperatively, it is scarcely noticeable. The apparent explanation for this is that she required considerable time to recover from vasomotor and pilomotor instability. The hypermetabolism was a striking feature in both cases. It is probable that hyperthyroidism was not present in either case and in 1 the hypermetabolism disappeared postoperatively. The diagnostic importance of a high urea clearance is stressed.

Coccidioidomycosis and Calcified Pulmonary Nodules—According to Aronson and his co-workers, in the course of studies dealing with tuberculosis among some of the Indians of the United States and Alaska, roentgen study of the chests of 3,024 children and young adults from 1 to 19 years who failed to react to the intracutaneous injection of 0.00002 and 0.005 mg of purified protein derivative of tuberculin revealed calcified pulmonary nodules. Among 704 children living on the Pima Agency, near Phoenix, Ariz., who did not react to tuberculin, calcified pulmonary nodules were observed in 102, among 419 Shoshone and Arapaho children living on the Wind River Agency, Wyo., only 1 of those who failed to react to tuberculin had a calcified pulmonary nodule, among 332 Chippewa children living on the Turtle Mountain Agency who did not react to tuberculin 15 had calcified pulmonary nodules, and among the 592 Sioux children of the Rosebud Agency and the 977 Indian children living in southeastern Alaska who failed to react to tuberculin 6 and 2 presented calcified pulmonary nodules. Because of the high incidence of calcified pulmonary nodules in 'tuberculin negative' children living on the Pima Agency the possibility that the nodules were coccidioidal was investigated. A large percentage of children of school age living on the Pima, San Carlos and Sells agencies and a small percentage of those living on the Fort Apache Agency (respectively 83.6, 92.9, 94.2 and 14.9 per cent) reacted to the injection of 0.1 cc of a 1:1,000

or of a 1:100 dilution of coccidioidin, while in other areas of the United States and Alaska but few (from zero to 59 per cent) reacted to these amounts or to the injection of a 1:10 dilution of coccidioidin. Some of the children living on the Fort Apache Agency who reacted to coccidioidin had attended school at the Pima Agency for several years, while others had visited or lived on the San Carlos Agency. That there was no relation between the coccidioidin and the tuberculin reaction was deduced from the fact that of 285 Alaskans tested simultaneously with purified protein derivative of tuberculin and coccidioidin 96 per cent showed reactions to tuberculin, with severe reactions occurring in many, and no reactions to coccidioidin and only 3 reacted to 0.1 cc. of a 1:10 dilution of coccidioidin. Failure to react to tuberculin in those showing calcified nodules cannot be attributed to allergy, since in 56 of 62 such persons the tuberculin reaction became positive one year after the intracutaneous injection of BCG vaccine. The data suggest that the nodules may be due to pulmonary infection with *Coccidioides immitis*.

Insulin Shock Therapy—Olsen has employed with success two new procedures in avoiding secondary hypoglycemic shock, especially in the struggling patient, due to irregular absorption of insulin, vomiting, refusal to take food or unknown factors. They are the intravenous injection of insulin to induce shock and the substitution of starch for sugar at the termination of the shock. The intravenous injection of insulin would be wasteful in routine diabetic practice because of its curtailed period of effect, but it is of real advantage in the treatment of psychosis where a limited period of action is desirable. To terminate the shock the dextrose injected intravenously is followed by the ingestion of a pint of thick potato soup, cooked cereal or any puree of dried bean, pea or lentil. The author gives about 100 cc. of a 25 per cent solution of dextrose at one intravenous injection and a pint of starch material within ten or fifteen minutes of the patient's awakening. Secondary shocks may still occur.

Sulfathiazole Emulsion—Ackman and Wilson have treated hundreds of cases of abscesses, carbuncles, furuncles and burns with an oil in water emulsion of sulfathiazole. The emulsion introduces a new method for the topical use of the sulfonamides in an old and well established "curtain drainage" medium. The

emulsion is made up of 5 per cent of finely powdered sulfathiazole, 2 per cent of triethanolamine, 24 per cent of water, 5 per cent of beeswax and 64 per cent of liquid petrolatum. The treatment is recommended for all burns on critical areas. For burned surfaces, single layers of emulsion impregnated strips of finely meshed sterile gauze are applied. Over the strips ordinary gauze dressings thoroughly impregnated with the emulsion are applied. In early stages particularly they are reinforced with dry absorbent material with or without a pressure bandage. This type of dressing and splint results in a minimal decrease of serum. The first redressing is decided by whether much serum is lost or whether further cleansing is desirable. Because the staphylococcus is a frequent invader it is advisable to make five days the time limit for changing dressings in deep second and third degree burns. The dressing has an immediate and continued local anesthetic effect. This decreases shock and minimizes the necessity for sedatives. The dressings are comfortable, soft and pliable, and they do not appreciably restrict movement. The emulsion dressing has been applied directly over Reverdin and Thiersch grafts all of which have thrived. There has been little exudate, no infection and no odor. This is evidence against any local tissue toxicity from sulfathiazole. The use of the emulsion as a burn dressing does not replace tannic acid or other eschar protective coverings necessary to prevent serum loss in large surface burns on the torso. However, on critical areas where the prevention of contractures is of utmost importance and disability precludes the use of an eschar the dressings are indicated, as they do not inhibit movement, are relatively painless and may be readily changed with minimal bleeding. The healing of burns is hastened by bacteriostasis, separation of the necrotic surface is accelerated by the softening effect, granulation tissue is stimulated and thus recovery is hastened.

Pathogenesis of Chronic Atrophic Pylonephritis—Taylor reports 3 cases in which the essential lesion was the destruction of large numbers of glomeruli by a fibrotic process originating from an ascending infection in the tubules leading to a periglomerular fibrosis, complete obliteration of the vascular tufts and a varying degree of arteriosclerosis and arteriolar sclerosis. Such a reaction must lead to renal ischemia so that it may be assumed that renin is released and angiotonin with the production of hypertension in a manner similar to that obtained in experimental hypertension, is formed subsequently. Therefore it is suggested that, to have hypertension associated with chronic atrophic pylonephritis, sufficient vascular damage due to progressive glomerular fibrosis or pronounced arteriosclerosis must be present to upset the "inhibitor-angiotonin" balance. Such arteriosclerosis might be present in one kidney without an associated hypertension, because then the inhibitor substance present in the normal kidney counteracts the action of the angiotonin released by the diseased ischemic kidney. However, if the other kidney is sufficiently diseased to decrease the inhibitor substance, the pressor substance can act unhindered and consequently hypertension results. The same pathologic process, with a different etiologic basis, may explain the persistent hypertension in chronic glomerulonephritis, in which there is also a progressive fibrosis of the glomeruli.

Suppurative Parotitis—McCormick employed 200 kilovolt roentgen therapy in the treatment of 19 cases of parotitis (with bilateral involvement in 6) and 1 case of bilateral submaxillary adenitis. Sixteen cases followed an operation. Five of the operations involved the pelvic organs or large intestine. Treatment of the condition is an emergency. The involved area was irradiated with 150 to 200 roentgens at a skin target distance of 50 cm., through a port of usually 10 by 15 cm. and filtered by 0.5 mm. of copper and 3 mm. of aluminum or 1 mm. of copper and 4 mm. of aluminum. The same treatment is given on each succeeding day until adequate improvement results. Usually pain is relieved almost immediately and the temperature falls. The gland may not show any objective change until the second day, when it rapidly resolves. Treatment within six hours of onset gives most satisfactory results. Within seven to sixteen hours resolution will occur in many cases, after sixteen or more hours patients should also be irradiated, as they may yet obtain a satisfactory resolution, but, if not suppuration takes place more quickly and clears up sooner than in

nonirradiated patients and there is considerable relief from pain. Surgical intervention should be delayed. It consists of a simple incision. Irradiation reduces the morbidity and high mortality of the disease. Four of the 20 patients died.

Thyroid Degeneration and Premature Aging—Hogg carried out experiments in white mice to confirm the observation of McGregor on premature aging of patients who are the subject of cystic degeneration of the thyroid, especially when the cyst replaces existing fetal adenoma. Fluid obtained from thyroid cysts (degenerative or fetal) in a dose of 0.6 cc was extremely toxic to mice, causing death in a few hours. It could be injected in smaller doses with safety. Animals so treated became sensitized to the material. Injection after a period of rest caused rapid death by what appears to be an anaphylactic reaction. Intraperitoneal injection of all different types of thyroid cystic material caused complete thymic atrophy. Of the animals treated with cystic thyroid material, 65 per cent showed hair changes; the fur became sparse and coarse. This is a recognized sign of age in mice. No control animal showed these changes. The treated mice did not lose weight but did lose sexual activity. Intraperitoneal injection of suspensions of thyroid extract in distilled water was not followed by any evidence of organic changes.

Utilization of Vitamin C by Cancer Patients—Minor and Ramirez estimated the amount of vitamin C that 7 control subjects, 1 patient with a localized cancer and 5 with metastatic cancer utilized; the respective averages were 67, 68 and 125 mg. The subjects were given a diet free of fruit and vegetables, and as there is no evidence of an endogenous supply in man their

daily supply comprised the 500 mg given parenterally and the estimated 10 mg in the diet. The daily utilization was calculated as 500 mg less the twenty-four hour urinary excretion. A possible explanation for the increased utilization of vitamin C by patients with metastatic cancer is apparent if the presence of an active carcinogen in such patients is postulated and that an interference with cellular respiration by this agent might cause a compensatory accumulation of ascorbic acid in the affected tissues and thus diminish the excretion of vitamin C.

Testosterone Therapy of Male Eunuchoids—According to Lissner and his associates, 5 typical eunuchoids whose improvement was previously successfully maintained by parenteral, implantation and/or oral administration of testosterone continued in their improved status on testosterone sublingually. In only 1 of the 5 was less testosterone required sublingually than orally. The patients preferred swallowing tablets to dropping a solution under the tongue. Four hypogonadal patients with no previous testosterone therapy were subjectively and objectively benefited from the sublingual administration of testosterone compounds. Larger doses of methyl testosterone would have been required orally to accomplish equivalent results. Sublingually, free testosterone was more effective than methyl testosterone or testosterone propionate. The androgen to be used was dissolved in propylene glycol so that 0.2 cc contained 5 mg of the testosterone compound.

Progesterone Therapy and Progestin Metabolism in Abortion—Progesterone was used by Davis and his co workers in an attempt to bring the pregnancy of 54 patients to viability. Of the patients 16 had histories of two or more previous spontaneous abortions, 30 had vaginal bleeding during the first twenty-eight weeks of pregnancy, with or without the accomplishment of pain, and in 8 abortions were progesterone. Pregnancy was maintained respectively in 50, 57 and 75 per cent of the women. Thyroid substance was an important therapeutic adjunct. Androhydroxyprogesterone orally was apparently as efficient as injected progesterone. The sodium pregnandiol glucuronide excretion of 14 patients was studied and 6 of the 7 who excreted normal amounts went to term, 4 with initially and continuously low levels aborted or miscarried and 3 who had normal levels followed suddenly by zero or near zero values aborted or miscarried within a few days of the drop.

Reduced Blood Pressure and Pyrogenic Reaction in Hypertension—With the theory in mind that renal ischemia is the primary causal factor of hypertension and that repeated renal hyperemia might have a favorable effect on the hypertension, Chasis and his associates repeatedly administered pyrogenic inulin, triple typhoid vaccine and tyrosinase by intravenous injection to 8 subjects with essential hypertension and 1 with chronic diffuse glomerulonephritis. The blood pressure was reduced significantly and maintained at reduced levels by repeated injections of the material. The hypotensive effect can be obtained without a rise in body temperature by premedication with aminopyrine. The mechanism responsible for the persistently reduced blood pressure is unknown, but from the more immediate effects of pyrogen it appears to be due in part to an adverse or asthenic action on the cardiovascular system rather than to the correction of the fundamental disturbance underlying the hypertension. Any pyrogenic material should be administered cautiously, since an alarming degree of peripheral circulatory failure may follow. One of the patients had this experience.

Dark Adaptation and Vitamin A in Blood—The relation between dark adaptation, the plasma level of vitamin A and the plasma carotenoids was investigated by Haig and Patek in normal persons and in patients with hepatic cirrhosis. There appeared to be no sex difference in the dark adaptation of 37 normal subjects, but in determinations of the plasma vitamin A and total carotenoid levels in 44 normal persons the mean vitamin A level for women was 14 per cent lower than that for men, while the mean carotenoid levels were the same in the two sexes. Sixty-seven simultaneous dark adaptation tests and plasma vitamin A and carotenoid measurements were obtained in 14 normal persons, 18 persons with cirrhosis of the liver and 7 persons with various other chronic diseases. If the cirrhotic and normal groups are considered separately, no significant correlations were observed between the plasma vitamin A or the plasma carotenoid levels and the dark adaptation values, but when the two groups were considered as a single population a degree of correlation between the dark adaptation measurements and the vitamin A values became apparent. Since the data of the several groups were not randomly distributed over the same range of values, it seems that the correlations arise from a tendency of the data to group themselves according to the separate clinical categories, the cirrhotic patients being at one end of a series and the normals at the other. This tendency for patients with hepatic cirrhosis to have higher dark adaptation and lower plasma vitamin A values than normal controls has been previously observed by others. It is possible that these correlations are attributable to factors other than a direct dependence of the retina on the level of vitamin A in the blood.

Exercise and Drug Effects on Electrocardiogram

The changes in the electrocardiogram following exercise, epinephrine, ergotamine tartrate, atropine sulfate, mecholyl and pressure on the right carotid sinus were studied by Hartwell and his co workers in 5 normal subjects with normal electrocardiograms. Each experiment was preceded by a period of rest until the pulse and blood pressure were stabilized. Exercise lowered the T waves of lead 2 in all electrocardiograms, the T wave in lead 1 was lowered in all but 1 subject and the T wave in lead 3 was lowered in 2 subjects and elevated in 1. Epinephrine lowered all the T waves of the three leads in 3 subjects, while in 1 the wave in lead 1 and in 1 the wave in lead 3 was not changed. The effect was maximal in ten to fifteen minutes. One subject showed frequent ventricular premature beats, while another 1 showed a varying PR interval with inverted P waves for a few minutes after 1 cc of 1:100,000 of epinephrine intravenously. Ergotamine raised all the T waves of the three leads of the 5 subjects, except that the T wave in lead 2 of 1 subject showed no change. The effect was maximal in thirty to sixty minutes. Atropine lowered all the T waves of all leads in 3 subjects and lowered all but the T wave of lead 1 of 1 subject and of lead 3 of another subject. In 1 subject an auriculoventricular nodal rhythm developed twenty minutes after the injection of atropine. By forty minutes this had changed to sinus tachycardia. Mecholyl lowered all the T waves in all leads. Tachycardia developed in all 5 subjects within one to one and a half minutes after its administration. The blood pressure of 4 subjects fell. Pressure on the right carotid sinus slowed the pulse, increased the amplitude of all the T waves in lead 3, elevated the T waves in lead 1 and lead 2 of 2 subjects and decreased the T wave of lead 1 in 1 subject. If a "repeat" electrocardiogram is taken after a patient has been given atropine, epinephrine or mecholyl it should be remembered that the foregoing changes can be due to the effect of the drug.

Antistreptolysin Titer in Chronic Glomerulonephritis

—The serum antistreptolysin titer response of 81 patients with chronic glomerulonephritis was studied by Earle and his associates. Necropsies performed on 13 of the 24 known to have died revealed chronic glomerulonephritis, in 23 others typical attacks of acute glomerulonephritis or of an exacerbation of chronic glomerulonephritis seem to have established the diagnosis beyond doubt, and in the remaining 44 the opinion of several experienced observers was that there was no evidence of renal disease other than chronic glomerulonephritis. The patients have been observed over periods of four months to

eight years. In 61 patients there were one hundred and one significant rises in antistreptolysin titer. Eighty-five of these rises form the basis of the present study. The rises were of value in detecting the hemolytic streptococcus etiology of many infections from which group A hemolytic streptococci could not be isolated from the pharynx. A number of instances of chronic upper respiratory infection from which group A hemolytic streptococci were repeatedly cultured but which were unassociated with rises in antistreptolysin titer were designated as the "carrier state." The study of certain factors affecting the antistreptolysin titer response in chronic glomerulonephritis revealed the following results. Sex had no effect. In general, children exhibited greater titer response to infection than adults. The character of the preceding hemolytic streptococcus infection ("deep" or "superficial") did not affect the magnitude of the response. In general patients with "nephrotic" edema exhibited smaller rises than did those without edema.

Atrophic Gastritis and Gastric Cancer.—Since 1936 Shapiro and his associates have performed satisfactory gastroscopic examinations on 124 patients with chronic atrophic gastritis and on 50 patients with gastric cancer proved at operation or necropsy. They attempted to determine whether there is any relation between gastritis and gastric cancer by repeatedly examining patients with atrophic gastritis to detect the early development of gastric cancer. In addition, 35 of the 50 have been studied with particular emphasis on the presence or absence of atrophic gastritis. Microscopic evidence of atrophic gastritis was found in 28 of the 35. Atrophic gastritis was often overlooked gastroscopically in the presence of gastric cancer. Gastritis occurred more frequently in patients having a long history of digestive disturbance. Gastritis and the presence or absence of free hydrochloric acid were not related to the location of the tumor. Achlorhydria and anemia occurred more often in patients with atrophic gastritis. The frequent coexistence of the two diseases strongly suggests a relationship.

Vitamin C Requirements of Children.—The vitamin C requirements of 5 children were determined by the Robertses, who found that 65 mg. of ascorbic acid was required by the 2 children 7 and 9 years of age and 75 mg. by the 3 who were respectively 10, 11 and 12 years of age to promote saturation on the basis of a 50 per cent excretion of the test dose in twenty-four hours. These amounts also maintained blood levels above 0.7 mg. per hundred cubic centimeters and allowed for average retention. All the children gained a substantial amount in weight during the study.

Sulfonamide Drugs in Urine—The presence of sulfonamide drugs in the urine can be determined qualitatively by the addition of 1 cc of a 2 per cent solution of pyridimethylamino benzaldehyde to 10 cc of urine cooled to room temperature. The method, Monto points out is unsuitable for jaundiced patients or for patients whose urine contains abnormal amounts of urobilinogen. The testing solution is best kept in a dark container. If the specimen of urine contains less than 25 mg of the drug per hundred cubic centimeters a yellowish green precipitate appears. If the concentration is above 250 mg a heavy orange precipitate appears.

Functional Chest Pain—In reviewing the records of 227 patients complaining of pain in the chest not due to rheumatic, hypertensive, arthritic or periarthritic heart disease but who had been advised that their distress was due to heart disease, Goodrich and Keyes found that organic disease was present in 43, the diseases were coronary arterial occlusion, dissecting aneurysm, pericarditis, pneumothorax, pulmonary infarction, acute fibrinous pleurisy, metastatic carcinoma and pneumocele, acute myositis and in 19 the pain was referred. Thus of the total 165 were experiencing distress of functional origin. In 93 this distress was judged to be angina pectoris and in 72 the distress was due to symptoms of noncardiac origin, that is cardioneurotic distress, in which the therapeutic problem for the physician is no less difficult. Factors other than fear about the heart contributed to the mental anxiety of most of the 72 patients. Evidence of neurotic tendencies was frequent. These included sighing respirations, absent gag reflex, tremor of the tongue or eyelids, reduced threshold for pain, globus hystericus and neurocirculatory asthenia. The term cardiac neurosis is used to designate hypochondriasis—a type of psychoneurosis with fixation on the heart. These patients had previously had and will later have symptoms of neurogenic origin relating to other organs.

Sulfathiazole Ointment for Pyogenic Dermatoses—Glicklich used sulfathiazole ointment in the treatment of 42 patients with impetigo, pyoderma, eczematoid dermatitis and recurrent herpes simplex, herpes zoster, infantile eczema, disseminated neurodermatitis and stasis eczema with secondary infection. The pyogenic lesions healed in three to nine days the average being five days. The strength of the ointment, whether 5, 10 or 15 per cent, made little difference in the rapidity of healing. From the results obtained the oral use of sulfonamides for treating minor pyogenic dermatoses is not warranted because of the danger of toxic manifestations invasion of the blood stream from localized lesions and because such use of the drug should be reserved for more serious illnesses.

Amphetamine Barbiturate Therapy in Psychiatric Conditions—During the last four and a half years Davidoff and Goodstone have used sodium amylal and amphetamine sulfate in combination for the treatment of psychotic and psychoneurotic patients. Patients with manic-depressive psychosis, depression,

psychoneurosis, reactive depression and depressed psychoneurosis responded well. Sixty per cent of patients with incipient dementia precox of the catatonic type manifested some improvement. Follow-up study disclosed that 5 with schizophrenia have relapsed, 2 of these were of the catatonic group. Patients become more cooperative and tractable to the hospital routine. As the treatment has some prognostic value in that it gives some idea of the patient's plasticity and inherent capacity to improve, it is of some use in investigating and in understanding the patient and can be used as a preliminary procedure to other therapeutic methods. It has proved of value in the treatment of alcoholism and those organic conditions occurring with behavior disorders of children.

Human Bites—Boyce reports 90 cases of infection resulting from human bites or injuries by human teeth. Sixty of his patients were Negroes, 71 were males of the ages between 9 and 68 years. The lesions included necrosis of soft tissue, tenosynovitis, thenar and palmar space infection and dorsal subcutaneous and subaponeurotic space infection. Osseous involvement was revealed roentgenologically in 21 and articular involvement in 8. Three patients were seen within twenty-four hours of their injuries, 36 between twenty-four hours and seven days and the remainder between eight and forty-two days. The constitutional reaction was manifested by chills, elevated temperature, headache and malaise. Some degree of leukocytosis was not unusual. The possibility of a bite should be borne in mind in any hand injury, particularly in one in which there is a foul discharge, and an endeavor should be made to elicit the true history. To close a human bite is the worst possible treatment. The treatment in early cases is the conversion of the anaerobic state to an aerobic state and the excision of devitalized tissue in which the fusiform bacillus and spirochete might readily grow in symbiosis. Thorough cleansing with soap and water should be carried out for ten minutes, and before the depth of the wound is determined it should be thoroughly irrigated with isotonic sodium chloride solution or clear sterile water. Devitalized tissue is then excised under anesthesia well beyond the area of injury. Injured tendons are not repaired, and no plastic work is done. If the joint capsule has been opened, collar incisions should be made in the adjacent web spaces to secure adequate drainage. The injured part is splinted, in hyperextension if the extensor tendon or articular space has been injured. Compression for the first several days should not cause edema or maceration. The dorsum of the hand is directed downward to promote drainage by gravity. Treatment

in later cases depends on the pathologic condition present. Simple compression is sometimes effective, particularly if cellulitis and lymphangitis are present. The wound should be widely opened under anesthesia, with drainage or debridement or both carried out according to the indications. Amputation should be done without delay if a roentgenogram shows irreparable osseous involvement. The patient must be hospitalized and kept in bed with the hand immobilized. Constitutional treatment is carried out as necessary. Infections due to bites should be treated according to the anatomic principles followed in any other infection of the hand, and incisions, for the sake of future function, should be as conservative as is consistent with adequate drainage. Of the author's patients 36 were treated by incision and drainage, 5 by debridement, 2 by osteotomy, 3 by partial amputation of a finger and 21 by complete amputation of a finger, in 4 also a partial removal of a metacarpal bone and in 1 amputation of the arm was necessary. The period of hospitalization was one or two days in 24, eighty-seven days in 1 and between one week and seven weeks in the others. One patient died of pneumonia on the sixty-seventh day of hospitalization and the eighty-eighth day after injury.

Paralysis of Laryngeal Nerve and Antitetanic Serum—Floyd and his co-workers report what they believe to be the seventh case of paralysis of the left recurrent laryngeal nerve and of both brachial plexuses following a subcutaneous prophylactic administration of 1,500 units of antitetanic serum. The patient gradually improved, and within three and a half months the function of the arms was normal. The voice gradually returned to normal, and within six months of onset the larynx appeared normal on inspection.

- *Treatment of Carcinoma of Prostate with Estrogens W M Kearns Milwaukee—p 575
Joint Responsibility of Obstetrics and Pediatrics in Problems of Newborn A H Parmelee Oak Park Ill—p 582

Treatment of Carcinoma of Prostate with Estrogens—Since the fall of 1940 Kearns has used estrogen for the treatment of 37 patients with carcinoma of the prostate. The diagnosis was established by rectal palpation, perineal biopsy, prostatic resection, skeletal and chest roentgenograms, blood phosphatase estimations and blood sedimentation rates. The ages of the patients ranged from 48 to 86 years, the average being 66.6 years. Seven patients have died and 30 are still under observation. The deaths were due to pulmonary embolism after cystotomy, acute pyelonephritis and uremia, pyelonephritis and generalized sepsis, bronchopneumonia, acute cholecystitis and cholemia or cerebral hemorrhage and pneumonia. There were 5 instances of intercurrent causes of death, as in only 2 did the progress of the carcinoma appear to be the cause. At the beginning 1 mg of diethylstilbestrol was administered by mouth three times a day for two to three weeks. The dose was then reduced to 2 mg daily for two to four weeks and then indefinitely to 1 mg. Clinical improvement, gain in weight, relief from pain throughout the body, improvement in blood counts, slowing of the sedimentation rate and a near normal phosphatase estimation was remarkable. After four or five months, improvement in the skeletal metastasis is noticed in the roentgenograms. In the prostate itself the gland not only shrinks in size but loses its dense nodularity, fixation and indistinct outline. After two months this change is unquestionable. Nine patients had gastric irritation, but it was lessened when the medication was taken with milk. Only 3 patients were not benefited.

*Sterilization of Surgical Rubber Gloves W J Stuart—p 694

Observations on Treatment of Scabies—In comparing the therapeutic action for scabies of benzyl benzoate, dimethyl-thiurathine and tetrathylthiuram monosulfide, Gordon and Serton found that all three when mixed with an equal quantity of a vegetable oil penetrate the skin within fifteen minutes of their application. Bathing should not be omitted if facilities are available. The most satisfactory results, irrespective of the drug used, come from clinics where the treatment is carried out under skilled supervision, or from the services, where the patients are under discipline. Often it is useless to treat a patient unless his contacts also are treated. Therefore centers should be provided for adequate treatment if the present epidemic is to be controlled. A comparison in rats of the effects of the three sarcopticides reveals that all or almost all the mites were killed within three days but tetrathylthiuram monosulfide had the most rapid action within twenty-four hours. The eggs were more resistant to treatment than the mites. The action of benzyl benzoate and dimethylthiurathene on the eggs was inferior to tetrathylthiuram monosulfide. A single application of any of the drugs was probably insufficient to produce a cure, therefore in human scabies a second application of the drug should be made after a week, by which time any viable eggs would have hatched. Tetrathylthiuram monosulfide should be given a clinical trial.

Sterilization of Surgical Rubber Gloves—Stuart presents facts on the sterilization of every pair of rubber gloves that he used during more than thirty years of private practice. Sterilization by steam at a pressure of 5 pounds for twenty minutes was efficient, provided all air was removed from the sterilizer and a piece of gauze extended from the inside of the tips of the fingers out to the opening of the cuff. This assures the entrance of steam. There was no increased deterioration with increased pressure up to 7 pounds. Thereafter deterioration was progressive. Boiling caused more deterioration than steam sterilization. About nine or ten operations may be expected from a good brand of gloves at the present time. Thirty years ago the average number of operations was eighteen or more per pair of gloves, by 1920 it was fourteen and there has since been a progressive diminution. Sterilization by soaking in an antiseptic is not adequate because it is uncertain, especially as in actual use the rubber is stretched and it deteriorates. If a slight trace of antiseptic remains inside the glove, the skin of the surgeon's hands is soon damaged, and if the remaining antiseptic is washed out in sterile water each washing involves a risk of contamination.

*Plague Vaccine R M Dowdeswell—p 26
Some Unusual Clinical Manifestations of Plague F J Wright—p 29
Clinical Aspects of Lung Complications of Plague G Goldstein—p 33

Plague Epidemic in Nairobi—In eleven months 547 patients with bubonic plague were admitted to the two civil hospitals in Nairobi. Plum attended most of the postmortem examinations at the Native Civil Hospital. The cases can be divided into an early period of hemorrhagic lymph nodes and septicemia, a middle period of septicemia with pulmonary signs and a late period of primary pulmonary signs. Of the 547 patients 354 died. Sulfapyridine was used at both hospitals. All but 2 of

the 131 patients recorded as having pneumonic or septicemic plague died. Sulfapyridine was used at the Infectious Diseases Hospital, where the majority of cases were bubonic. If given sufficiently early and in large doses, it acted almost as a specific. Most patients who recovered had a normal temperature by the second or third day. The relation of the duration of illness before treatment to prognosis is seen by the following: Of 33 giving a history of one day 4 died, of 72 giving a history of two days 16 died, of 17 giving a history of three days 6 died and of 40 giving a history of four or more days 35 died. The average dose of sulfapyridine used in an adult case was 4 tablets on admission and thereafter 2 tablets every two hours until the temperature had been normal for twenty-four hours.

Pathology of Plague—From a study of the reports of pneumonic plague in other parts of the world, Vint is convinced that Kenya is not likely to suffer from an epidemic such as that of the historical pneumonic plague. But this does not mean that it is immune from small outbreaks, which will affect not only the African and Asiatic communities but also the Europeans. It is more or less useless to examine for plague rats caught in a baited trap. A plague rat is a sick rat and will not be attracted by food in a trap. The rat that is already dead is the one that must be searched for. When dead rats are found so decomposed as to render microscopic detection impossible, smears should be made from the bone marrow.

Plague Vaccine—According to Dowdeswell, the available evidence regarding the use of plague vaccine shows that a high degree of protection can be obtained in animals, and as a consequence there is good reason to expect some immunity in man. Field experiments support the contention that plague vaccine affords considerable protection. However, recourse to vaccine does not excuse those responsible for the health of a community or individual prosecution of the fundamental hygienic control measures.

Sulfamethazine—Macartney and his associates used sulfamethazine for the treatment of 73 cases of pneumococcal lobar pneumonia and a few cases of meningococcal meningitis and gonorrhea. The total fatality for the 73 cases was 5, 4 were bacteremic, 10 other patients with bacteremia recovered. Improvement was generally noticed within twenty-four hours after treatment was begun. It was similar to that following sulfapyridine therapy only that the patients did not complain of the severe mental and physical depression which often accompanies sulfapyridine treatment. Cyanosis was not observed, while nausea and vomiting occurred in only 5 and were not sufficient in degree or duration to interfere with the continuation of oral treatment. Complications developed in only 2 patients, pneumococcal meningitis developed in a woman of 52 who died, and slight jaundice developed three days after the

cessation of treatment in a man who made a good recovery. The results obtained with the drug in 6 cases of meningococcal meningitis (recovery in all) and 9 of gonorrhea in the male (satisfactory tests of cure after two weeks of treatment) indicate that the preparation is likely to be highly efficient. The preparation, because of its high solubility, is unlikely to cause renal damage.

Vitamin C Levels of School Children and Students—Comparison of vitamin C levels before and during the war (winter season) of two groups of boys (one residing at an institution for waifs and strays and the other attending a poor class elementary school in the same town) revealed to Harris that there had been a considerable drop in the levels of both groups. Before the war the dietary at the residential institution included an orange daily. In peacetime the levels were notably better at the well managed institution than among the boys from the poor homes. Before the war all the boys at the institution on the improved diet were up to standard but at the corresponding season during the war 21 out of 33 were slightly below standard and 4 were more severely below standard (needed four or five days of dosing). As many as 16 out of 29 boys from poor homes were in the latter category, and 2 of them remained unsaturated after five days. Tests of the boys at the institution at the close of the 1941 summer proved that notwithstanding the war, the reserves were excellent. Similar tests carried out during wartime on 12 research workers, 7 medical students and 16 members of a woman's college showed on the whole that they were affected less than the poorer children in their reserves of vitamin C but again there was evidence of a strong seasonal tide. The level of the woman members at the end of the summer was highly satisfactory. The results confirm the need for care in insuring adequate intakes of potatoes and greens as sources of vitamin C in winter.

Saturation Method for Determining Vitamin C Levels—Harris concludes that the saturation method of determining vitamin C levels is reliable. He studied its relation to the following points: specificity, standards representing saturation, fluctuation in excretion after saturation, individual variation, influence of fever or other factors, relation to blood level, variation in individual requirement in relation to body weight, standards accepted for the daily requirement, the reality of subclinical deficiency, significance of saturation for health, lack of "reserves" of vitamin C and the possibility of adaptation.

Vitamin C Survey of Medical Students—The vitamin C level of medical students as determined by the saturation test between May and July 1939 in 87, in July and September 1940 in 42 and in June and July 1941 in 52 shows that as far as "saturation" is concerned the condition of the subjects after the first nine months of war was not significantly different from that of twelve months earlier but in June and July 1941 (about twenty-one months after the outbreak of war) the subjects showed a much greater degree of unsaturation. Francis and Wormald state that this deficiency was on an average about one and a half large doses per subject (equivalent to about 1.5 Gm. of the vitamin).

Calcium and Phosphorus Excretion in Thyroid Disorders—Robertson attempted to determine the mechanism of the increased excretion of calcium in thyrotoxicosis and myxedema. He found that in untreated thyrotoxicosis the serum calcium and inorganic phosphorus are diminished, subtotal thyroidectomy, in the absence of any impairment of the parathyroids, causes the serum calcium and inorganic phosphorus to return to normal. The loss of calcium is only in the urinary output, the fecal loss is essentially normal. Iodine causes a significant diminution in the mean calcium output, but the out-

put still remains above normal. The phosphorus loss is predominantly in the urine. Following iodine therapy the mean phosphorus balance returns to normal. Subtotal thyroidectomy lowers the phosphorus balance to below normal. There is a highly significant difference between the phosphorus balance of normal subjects and of thyrotoxic patients after a successful subtotal thyroidectomy. In untreated myxedema the serum calcium and inorganic phosphorus are normal while the serum phosphatase is diminished. With thyroid feeding the serum calcium falls and the inorganic phosphorus rises to a level which makes the calcium and phosphorus product the same after as before thyroid feeding. The serum phosphatase rises to normal. The calcium output is diminished. Adequate thyroid feeding increases the output to normal and the younger the subject the greater is the increase. The fall in calcium output affects only the urine, and the increased calcium output after thyroid feeding occurs only in the urine. The phosphorus balance is positive compared with a negative balance in normal persons. Thyroid feeding converts the positive balance to near normal. The diminution in output is in the urine. The fecal output is normal. The diminished phosphaturia is both total and relative. Thyroid feeding causes a great increase in the phosphaturia and at the same time a significant fall in the output of phosphorus in the feces to below normal. It is suggested that thyroxine directly affects the renal threshold for calcium. Excessive secretion of thyroxine in thyrotoxicosis lowers the threshold, whereas deficient secretion in myxedema raises it. The raised excretion of phosphorus in thyrotoxicosis and the lowered excretion in myxedema are probably secondary to the changes in calcium excretion.

Sodium Amytal and Intelligence Test Scores—To determine the practical usefulness of sodium amytal for reducing apprehension in time of stress, Slater and Sargent believed it necessary to have some notion of the degree to which it may impair the normal processes of thinking and the capacity to react calmly to an emergency. To this end they measured the effect of the drug on the thought processes of men who come into the hospital one week they were given a routine intelligence test and in the next week they were retested an hour before and after they had a capsule of the drug or dextrose (control). There was a drop of 3 to 4 points in an individual's intelligence quotient after taking the drug. This does not represent an appreciable decline in mental efficiency. Nearly 400 patients were tested to find whether the differential drop was large enough to be significant. Intelligence quotients vary much more widely among people in a single occupation, even when highly specialized. A variation of 3 or 4 points is not likely to affect seriously a person's working efficiency, when the ability of his competers varies between so much wider limits. Therefore it is concluded that sodium amytal in doses of 3 grams (0.2 Gm.) or less does not impair intellectual efficiency to any important extent. The actual dose employed in clinical practice will have to be chosen with individual susceptibilities and requirements. For those engaged on highly specialized work its effect on the special aptitudes involved should be separately tested.

Methylnaphthoquinone and Blood Clotting—The effect of 2 methyl-4 naphthoquinone on the clotting factors of the blood of 23 jaundiced patients with diminished plasma prothrombin was investigated by Stein. He observed that the plasma prothrombin responded in one of four ways: (1) prompt return to the normal level following a single injection of 5 mg in 15 patients, (2) delayed return to the normal level in 2, (3) a partial but ineffective response in 2 and (4) complete lack of response in 4. The last two ineffective responses occurred in the 6 patients with jaundice of hepatocellular origin. Therefore

the nature of the prothrombin response obtained is of great value in differentiating obstructive from hepatocellular jaundice. The blood proteins estimated for 6 patients with an effective prothrombin response were not materially affected by the naphthoquinone, the fibrinogen response of 2 was also ineffective. The serum calcium examined in 13 before and after the injection of naphthoquinone showed a type 1 prothrombin response in 9, a type 2 in 1, a type 3 in 2 and a type 4 in 1. The serum calcium variation as a result of the injection was inconsistent and most cases show but little change. The maximal increase was 1 mg; the maximal decrease was also 1 mg. The serum calcium thus shows no relation to the prothrombin index and is probably not a factor in producing increased coagulability of the blood seen by the rise in prothrombin. The erythrocyte sedimentation rate and packed cell volume determination in 14 patients before and after the injection of the naphthoquinone bore no relation to any alteration in prothrombin. The clot retraction estimated in 5, showed a significant increase in the serum volume index and clot retraction index in 3, and in 2 the serum volume index was unaffected. The lvs bleeding time as determined in 2 patients was essentially unaltered twenty-four hours after the injection of naphthoquinone, although the prothrombin index had reached a normal level.

Sulfonamidothérapie by Intraperitoneal Route—Jentzer and Calme experimented with intraperitoneal introduction of sulfonamides in rabbits and mice. They found that it is compatible with life to give comparatively large doses to rabbits when sulfathiazole is given as a neutralized liquid. The same doses of sulfathiazole in powder form (mixed with 4 parts of boric acid) kill the rabbits in several hours. The effect of the adjuvant body is responsible. Studies on the absorption and elimination disclosed that the blood concentration curve mounts quickly in the first two hours. The blood content becomes quite elevated. It declines rapidly up to the fifth hour, then the concentration is maintained at a low level for forty-eight hours. In mice subjected to a fatal infection exclusive intraperitoneal sulfanilamide therapy proved less effective than subcutaneous therapy. The authors believe that peritoneal infection will be benefited by a single intraperitoneal application of a neutralized liquid sulfanilamide preparation and that further treatment should consist of intramuscular administration followed by the oral.

Painful Abdominal Crises in Sickle Cell Anemia—Cabrera Calderin and his collaborators report the case of a Negro girl aged 11 who entered the hospital with acute abdominal symptoms. The symptoms subsided and the girl was dismissed. One week later she had another abdominal crisis and was again sent to the hospital. Several examinations, including roentgenoscopy of the vertebral column, were negative. The blood count disclosed 2,450,000 erythrocytes, 26,000 leukocytes, 40 per cent hemoglobin and falcular erythrocytes of sickle cell anemia. The attacks were interpreted as lumbosabdominal crises of sickle cell anemia. Blood transfusion produced great improvement, the painful crises subsided, but pressure still

elicited pain in the epigastric and lumbar regions. Several days later the girl had severe pain in the right elbow. This pain ceased following a blood transfusion and application of heat. Anderson and Ware ascribe the pain to splenic infarcts, stretching of the splenic capsule being the cause of pain. The articular pains are due to osseous changes. Examination of the blood is of greatest importance in the differential diagnosis, because otherwise sickle cell anemia might be mistaken for hemolytic jaundice, ovaleytic anemia, Lederer's syndrome, acute hemolysis or Cooley's anemia. Blood transfusions and liver therapy are helpful in the treatment. Possibility of sickle cell anemia should be considered in Negro patients or in half breeds exhibiting anemia and abdominal crises.

Leprosy with Acute Onset—Fonso Gandolfo and his collaborators point out that leprosy resembles tuberculosis in several respects including an acute onset. The initial lesions are usually seen on the uncovered portions of the body, the face and the hands. The initial lesions may be single or multiple. A single lesion may prove the existence of leprosy. A leprotic outbreak or a leprotic reaction capable of simulating various acute entities, in many cases can constitute the first manifestation of leprosy. This acute initial picture is often diagnosed as acute polyarticular rheumatism, septicemia, erysipelas, polymorphic erythema and the like. The acute onset of leprosy is comparatively frequent.

Chronic Tuberculous Cerebrospinal Leptomeningitis—Schmidt reports the case of a man, aged 28, who, since the age of 18, had presented obscure cerebral symptoms with convulsions, loss of consciousness and mental disturbances. Necropsy disclosed a chronic tuberculous cerebrospinal leptomeningitis with tubercles in the dura, internal hemorrhagic pachymeningitis, calcified foci in the tracheobronchial lymph nodes, inflammatory swelling and tuberculosis of the paratracheal and hilus lymph nodes of both lungs, pleural adhesions and catarrhal urocystitis with dilatation of the bladder, ureters and renal pelvis. Microscopic examination of the lymph nodes disclosed calcified tuberculous foci. The microscopic aspects of the brain are described in detail. There was evidence that the chronic tuberculosis of the leptomeninges had a strong tendency to cicatrization. The author cites 3 similar cases from the literature.

- Eugenic Marriage Consultation. H. Vellguth —p. 73
*Prevention of Tropical Diseases. E. Martini —p. 77

Prevention of Tropical Diseases—Martini points out that many tropical diseases are now more easily controlled than some of the diseases of the temperate zone. The reason is that chemical industry has developed effective drugs against tropical diseases, particularly against those caused by protozoa. Every

shortening of an infectious disorder by effective chemotherapy reduces the danger of dissemination. The patient who has been cured and no longer harbors the pathogenic organisms ceases to be a danger to his environment. The author mentions the use of quinine, atabrine and plasmochin in the treatment of malaria, the efficacy of germanin in trypanosomiasis, the use of antimony preparations in the leishmaniasis (kala azar, oriental sore), of emetine and chinofon in amebic dysentery, of ascaridol in hookworm diseases and of arsphenamine in relapsing fevers and frambesia. There remain yellow fever, dengue and sandfly fever, for which as yet there are no effective chemotherapeutic agents. Also in leprosy and diseases caused by *Schistosoma* chemotherapy is gaining ground slowly. It is important for the prevention of tropical diseases that some of the aforementioned chemotherapeutics can be used prophylactically. It was an error to believe that small daily doses of quinine would prevent malaria. Infection takes place in spite of this prophylaxis, although the manifestations of the disease are prevented. None of the malarial drugs prevent malaria and none completely remove the plasmodia from the organism, although plasmochin is said to reduce the possibility of relapse considerably. The prophylactic action of germanin in trypanosomiasis is more favorable. In diseases like yellow fever, in which chemotherapy has been disappointing, vaccination has made considerable progress. In addition to drugs and vaccines the interruption of the cycle of transmission is important. This is accomplished by sanitary disposal of wastes, isolation of cases of leprosy and eradication of the insect vectors in case of malaria and particularly of yellow fever. He also stresses the importance of screening houses. Hygiene in the tropics requires the collaboration of hygienist, entomologist and sanitation engineer.

Striatal Syndrome with Arthritis After Nitrous Oxide Anesthesia—De Haas reports the history of a man aged 45 who underwent a gastric resection under nitrous oxide anesthesia. He was cyanotic during the anesthesia, and his respiration suggested oxygen lack. There was arrest of breathing for two or three minutes. Artificial respiration and cardiac massage brought about first arterial pulsation followed by the return of respiratory movements. The cessation of respiration must have increased the cerebral anoxemia. Chronic hypoxemia was probably the main cause of a typical striatal syndrome and mild signs of a pyramidal tract lesion. The report is presented chiefly because the patient, who had never had articular complaints, had developed five weeks after the operation pain, redness and swelling of various joints of the arms and legs. The rheumatoid arthritis was associated with fever. It has been suggested that a connection exists between lesions of the corpus striatum (or substantia nigra) as found in paralysis agitans and conditions similar to osteoarthritis and chronic rheumatoid arthritis. Some investigators consider that all abnormalities of joints falling within the scope of rheumatism (therefore including rheumatic fever and acute rheumatoid arthritis) are primarily determined cerebrally. The case presented here may be of some significance in this connection. As far as the author knows, no such case has been reported before.

Dupuytren's Contracture and Epilepsy—Lund has not been able to find in the literature any attempt to correlate Dupuytren's contracture with epilepsy. His own observations at an institute for epileptic patients demonstrate that the two concur sufficiently often to suggest a pathogenic relationship. The literature on pathogenesis of Dupuytren's contracture

emphasizes the hereditary factor, chronic trauma, a neurotrophic disturbance and finally a fibroblastic diathesis, a tendency to mesenchymal hyperplasia. Dupuytren's contracture may manifest itself as simple nodular thickening of palmar fascia or this may be associated with the characteristic puckering of the skin, there may be active finger contracture or passive contracture. The author has examined 190 male and 171 female epileptic patients for the presence of Dupuytren's contracture, fibroma plantae and periarthrosis humeri. Among the males 22.6 per cent had nodules or thickened bands in the palmar fascia, 15.8 per cent had the characteristic puckering of the skin in the palm and 11.6 per cent had finger contracture. The percentages among the epileptic females were about half as high. Fibroma plantae was found in 13 males and 12 females, 22 of these had also Dupuytren's contracture. There were 12 cases of periarthrosis humeri, in 11 of which Dupuytren's contracture was present. One hundred of the males and 100 of the females were examined for "heloderma" (subcutaneous fibroma of the dorsal aspect of the middle joints of the fingers), which was found in 29 males and 13 females, 29 had Dupuytren's contracture as well as heloderma. One hundred of the males were examined for induratio penis plastica, which was found in 3 cases, 2 of these had also Dupuytren's contracture. A comparison with a control group consisting of 1021 workers doing hard manual labor showed that Dupuytren's contracture was four times as frequent among the epileptic patients as among the workers, the degree of the contracture seems to be more pronounced and the manifestation age lower among the epileptic. Among the workers there was only 1 case of fibroma plantae (0.1 per cent), among male epileptic patients 13 (6.8 per cent). Heloderma was about twenty times more frequent among the epileptic than among the controls. Future investigations should inquire into hereditary connections between epilepsy and fibroblastic diathesis, the possibility that these disorders are due to functional disturbances in the vasomotor system of epileptic patients (constant hyper-sympathetomy?) and (3) the question of whether prolonged treatment with phenobarbital could be responsible.

Chyle Cysts in Mesentery—The first of Malm's patients with cavernous lymphangioma with cyst formation was a girl aged 6, who gave a history of disturbance since infancy. Operation for occlusion revealed a flabby tumor, which had not been palpable originating from the mesentery of the small intestine and located in the lowest part of the abdomen. The tumor weighed 1060 Gm and contained chyle. In the second patient, a girl aged 12, the tumor, of long standing originated from the upper part of the mesentery of the small intestine, was palpable and contained 125 liters of chyle fluid. In both cases extirpation and resection of the intestine were followed by recovery. The author believes the chyle cysts to be true angiomas probably developed from embryonal germs.

Book Notices

Urology In War Wounds and Other Emergencies of the Genito Urinary Organs Surgical and Medical. By Charles A. Madsen. 11 (omdr (M C) U S N R. Cloth. Price \$2.15. Pp 78 with 27 Illustrations. Baltimore: Williams & Wilkins Company 1942.

This treatise was intended to be an elementary guide to medical officers who are unfamiliar with the recognition and treatment of genitourinary lesions observed in war. The chapter on traumatic lesions of the genitourinary tract is very brief, in fact, less than fourteen pages are devoted to this important phase of the subject. It embodies many excerpts from Dr H. H. Young's Practice of Urology and his other well known contributions to the subject of war lesions. It should be said that the illustrations are excellent. Included in the book is a chapter on uroesthesiology by Dr Tovell. This is an excellent epitome of practical uroesthesiology which could be applicable to any surgical field. It merits more general recognition. Also included is a good, although very brief, chapter on the subject of bladder dysfunction after acute cerebrospinal injury written by Lloyd Lewis. Although a monograph of this type may be of some practical value one wonders whether the inquiring medical officer would not gain more by a perusal of more comprehensive books and articles already published on the subjects involved.

Experimental Studies on the Vasomotor Innervation of the Retinal Arteries. By Kaj Ivarsen. The Translation into English by Robert Fraser. Denne Afhandling er af det medicinske Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad. Copenhagen 1941. Paper. Price 10 Danish kroner. Pp 201 with 55 Illustrations. Copenhagen: Fluor Munksgaard 1941.

This monograph, translated into English by Robert Fraser, appeared as supplement 17 of the *Acta ophthalmologica*. In chapter 1 the vascular circulation is discussed under subheads of general, vasomotor innervation of the cerebral arteries and vasomotor innervation of the retinal arteries. In these the author presents a comprehensive review of the literature. Chapter 2 reviews the vascular anatomy of the globe. In chapter 3 the author describes his method. He used cats and anesthetized with intramuscular injections of 0.5 to 0.6 cc per kilogram of body weight of butyl bromide malonylurea in divided doses. The pupils were dilated with atropine. The retinal vessels were viewed with a Leitz Ultrapak microscope with a contact glass on the corner. Recordings of vessel changes were made by the method devised by Fog. Caliber of the vessels was measured following intravenous injections, electrical stimulation and changes in intracranial pressure. Blood pressure and intraocular pressure were also recorded by kymographic tracings.

The reaction of retinal vessels to rise in blood pressure produced by epinephrine, compression of the abdominal aorta and increase in intravascular blood volume was studied. The author found that the tone of the retinal arteries during rises of the systemic blood pressure increases so much that the vessel contracts. The increase is not always great enough to resist exceptionally high pressures and the vessels dilate passively. Reducing blood pressure by injections of acetylcholine, stimulation of the depressor nerve, inhibiting heart action and diminution of intravascular blood volume were produced on several series of animals. The author concluded that retinal arteries dilate with a fall in blood pressure, regardless of how it is produced.

The retinal arteries are normally in a state of tonic constriction, which increases with a rise of blood pressure, with the result that the vessels contract and diminish when the pressure falls and the vessels dilate. The changes were due to alteration of blood pressure. The author attempted to discover whether the variations in blood pressure alter retinal artery caliber through the nerves by chemical or physical means. He stimulated the sympathetic nerves with a faradic current, produced rise of blood pressure by increasing the blood volume after denervations, produced a fall in blood pressure by reduction of volume after denervation and observed the arteries during asphyxia and injections of histamine. He concluded that regulation of tone of the retinal arteries is determined by the pressure variations themselves.

A study of the relation of intracranial pressure increase to retinal arteries led the author to conclude that the vessels respond to moderate increases by dilating. If the pressure rises to that of the systemic blood pressure the arteries are compressed and cerebral anoxia follows, causing a rise of systemic pressure, this in turn causing dilatation. His experiments showed that amyl nitrite caused a dilatation of the retinal vessels. Changes in intracranial pressure showed no causal relation to alteration in caliber of the retinal vessels. Porsaa concludes that he has proved that "retinal arteries and those of the brain in all respects behave physiologically alike." This monograph is of interest to students of vascular physiology.

You Don't Have to Exercise! Rest Begins at Forty. By Peter J. Stein. Cloth. Price \$1.50. Pp 207. Garden City: Doubleday Doran & Company Inc. 1942.

This is a small book with a large impact. It is a direct challenge to the popular belief, fostered by many promoters of the cult of the physical, that exercise is the sine qua non for physical fitness. It comes at a time when the nation has barely escaped—or has it?—the menace of a national program of exercise for all citizens, of whatever age or physical state, in the name of victory through "physical fitness." The theory that exercise is essential for the maintenance of bodily vigor into the upper age brackets is the stock in trade of many who view with alarm the protuberant abdomen of the bleacher athlete and point to his laziness as the cause of his unfitness. Quite the contrary, says this startling book, with commendable frankness and courage "Rest begins at forty." Never exercise if you can avoid it, after you have passed forty and lost the youthful urge to activity. Far from keeping you fit, it may hasten your breakdown and hurry you to an untimely death. Gardening and walking are the only exceptions.

The author explains his theory effectively, pointing out its sound biologic foundation. Active lives, in nature are short lives, deliberate lives are long. Witness the rabbit on one hand, or the mouse, and on the other the turtle and the elephant. Youth requires exercise, desires it normally and should have it. Age demands rest and must have it. Instead of exercise for those over 40 he recommends good posture, which gives the older muscles all the exercise they require, merely through maintenance of normal physiologic tone. Plenty of sleep, relaxation through hobbies, and judicious vacations (not crammed with exercise) complete his alternative program.

It is a delightfully blithe and breezy book, crusading with a ligh instead of the deadly seriousness of the reformer. The author is far from a reformer. All he wants is to give you the facts—take them or leave them. You'll suffer the consequences, if any, not he. Many doctors will read it with delight, for they have experienced the same situations he describes with patients addicted to exercise sufficient to kill two men and wondering why they "can't take it any more." It should be read by those same patients too. It is written for lay readers, to make them lazy readers and help them live longer by living more leisurely.

Heredity Food and Environment in the Nutrition of Infants and Children. By George Dow Scott. A.B. B.S. M.D. Consulting Pediatrician to the Lutheran Hospital New York City. Cloth. Price \$5. Pp 778. Boston: Chapman & Grimes Publishers 1942.

This volume by its title indicates the tremendous scope of its approach to the problem of nutrition for children. Sections on heredity and environment, the biology of mating, the growth of the cell and on disease in general precede discussions of metabolism and the discussion of infant nutrition. There are special sections devoted to each of the individual foods, the fruits, physical and psychic stimuli and physiologic processes. The scope of the volume is thus so great that it is far more likely to be considered a work of reference than a book easily readable or a textbook. It is interesting to observe that the section on oleomargarine fails to mention the recent action for enrichment of margarine with vitamin A. The section on cocoa and chocolate in the child's diet credits the eating of chocolate with the causation of tooth decay and fails to mention the frequent sensitivity to this substance. The author has surveyed a vast literature in compiling the information that is offered, and certainly his approach to the subject is in accord with modern points of view.

Behind the Mask of Medicine By Miles Atkinson Cloth Price \$3
Pp 348 New York Charles Scribner's Sons 1941

The unfortunate title of this book seems to indicate that it will reveal much that has been concealed yet it really does nothing of the sort. Indeed there has been so much written and spoken and otherwise displayed about medicine in recent years that many a layman seems to know more about what goes on than do the doctors themselves. Dr Atkinson with excellent literary ability discusses new advances in relationship to therapy, diagnosis, prognosis and other aspects of medical care. If any of his chapters approach revelations it is the one on excesses in surgery, yet every one knows that surgery has become much less difficult as the result of modern anesthesia and standardization and that, therefore, the tendency toward surgery is a little greater than it used to be. If one wished to quarrel with the author one might select for the purpose the chapter on 'Practice Ethical and Unethical'—yet he does not find any solution for the problem of fees. Particularly important is the section on the plight of the hospitals. This is a problem which today concerns all the nations of the world. The author offers several solutions for improvement but it is doubtful that any one has yet worked out a plan that will be generally satisfactory. The chapter on socialized medicine offers planning for the development of medical centers in areas with the hospital as the center. Something similar was proposed many years ago by Drs Frank Billings, Victor Vaughan and other leaders of a previous generation. Great Britain and the United States seem to be moving toward this plan but the details which the author dismisses somewhat too readily are after all the factors which will determine the success or failure. In his final chapter Dr Atkinson thinks that the world is going to be too tired after this war to start building a better world on the ashes of the old. That remains to be seen.

A Textbook of Bacteriology By Thurman B Rice A.M. M.D. Professor of Bacteriology and Public Health at the Indiana University School of Medicine Indianapolis Third edition Cloth Price \$1.50 Pp 560 with 119 illustrations Philadelphia & London W. B. Saunders Company 1942

This book is intended to serve as a practical rather than as a theoretical textbook for beginning students as well as general practitioners of medicine, dentistry and pharmacy. The subjects are discussed in a sketchy manner. For example in the chapter on the typhoid bacillus no mention is made of O and H agglutinins and of Vi antigen. In the discussion on the whooping cough bacillus no mention is made of the phase of the organism. The headings 'manner in which disease is produced' and 'lesions produced' are used in discussing each of the various pathogenic micro-organisms, but much of the discussion under them is concerned primarily with the clinical course of the disease. In many cases the manner in which disease is produced is unknown and the author offers a single explanation as factual. There are several inaccuracies, for example on page 296 *Vibrio septique* is listed as a synonym for *Clostridium sporogenes*. On page 299 under the prophylaxis of botulism the statement is made 'hence vegetables are liable to be contaminated—especially when grown in manured soil.' For practitioners who depend on this textbook for information there is much to be desired. The medical student must rely on lectures to supply the missing gaps in information.

Functional Pathology By Leopold Lichtwitz M.D. Chief of the Medical Division of the Montefiore Hospital New York Cloth Price \$8.75 Pp 567 with 157 illustrations New York Grune & Stratton Incorporated 1941

The book deals with certain aspects of functional pathology with penetrating detail but cannot qualify as a comprehensive textbook of functional pathology. It reflects only the interest and personal experience of the author. Were this book entitled "Studies in Functional Pathology" it would occasion definite pleasant surprises rather than general disappointment. Despite this observation, the reviewer feels that this book would enrich the library of physicians searching for the mechanism of obscure functional changes. It emphasizes a point of view at the expense of factual observations—hence the preponderance of references to the earlier work in physiology and pathology. The chapters

on the mechanism of blood diseases, hypertension and water metabolism are particularly well presented. The collection of photographs and arrangements of charts in themselves will easily compensate an interested purchaser.

To the credit of the author it is readily apparent that the discussions center about subjects of interest to him personally rather than attempt to cover an expansive field, and one fails to find the hackneyed expressions and errors that are usually carried over from one textbook to another. The book therefore is stimulating and thought provoking regardless of whether or not one can agree altogether with the author. The workmanship in printing, paper and binding is superb. Contrary to one's expectations the author reveals himself as an English stylist, and it is difficult to find any chapter in which the expressions appear either stilted or labored. It is hoped that this book will serve as a precursor to coming editions, with more emphasis being placed on the more recent physiologic advances and pathologic concepts developed in laboratories by men better known to the American reader.

Synopsis of Materia Medica, Toxicology and Pharmacology for Students and Practitioners of Medicine By Forrest James Carlson D.V.M. 3rd Edition Second edition Fourth Edition Price \$7.75 1p 699 with 46 illustrations St. Louis C.V. Mosby Company 1942

The first edition of this book, which has been written for students and practitioners of medicine, was reviewed in these pages a little over a year ago and its possible usefulness described by the statements 'It is inclusive, up to date, sufficiently exhaustive for ordinary textbook purposes and extremely readable. Many of Jackson's fine tracings and colored diagrams are borrowed to enrich its pages. The bibliographic references are numerous and evince the author's wide acquaintance with the literature of his subject.' While there has been no radical change in the plan of the second edition, the author has brought the information up to date and has removed a number of criticisms directed toward the first edition. The author's cognizance of late developments is attested by reference to U.S.P. XII, N.F. VII, heparin, coumarin compound, gramicidin, streptomycin, penicillin, pectin, blood and blood substitutes and the newer sulfonamides. This edition merits the popularity accorded the first.

Physiological Psychology By S. R. Hathaway The Century Psychology Series Richard M. Elliott Editor Cloth Price \$2.75 1p 34 with 11 illustrations New York & London D. Appleton Century Company Inc. 1941

Many physicians and psychiatrists are not aware of the fact that the training of modern psychologists involves a thorough knowledge of the form and function of the central nervous system. Several books have been published on this subject, which though brief, nevertheless serve as accurate complete and competent introductions into neural anatomy and physiology. Although the title of the present book is "Physiological Psychology" about an eighth of it consists of simple and accurate descriptions of nerves and of the anatomic features of the nervous system, including the microscopic and gross findings. In addition to the elementary neural anatomy and physiology there are excellent chapters adequately discussing the basic physiologic background of the emotions, speech, intelligence, consciousness, sleep and motivation. For a simple, competent and useful survey of the mechanics of behavior, this book should serve its purpose. It has a short but not unsatisfactory selected bibliography and a competent index. There is no annotation in the text to show whence the facts have been culled. The volume contains several line drawings showing nervous structure and graphs showing quantitative features of psychological traits.

Foundations for a Science of Personality By Andras Angyal M.D. 1st Ed. Resident Director of Research Worcester State Hospital Worcester Mass. Cloth Price \$2.25 1p 398 with 12 illustrations New York Commonwealth Fund London Oxford University Press 1941

There are innumerable theories of mental functions. Some as the gestalt theory, have to do with the integration of various thought processes, others, such as psychobiology, have to do with the integration of various fields of knowledge about the mind. Dr Angyal makes an attempt to fuse as many of these as possible into a single, scientific whole. Unfortunately his

approach to the subject is rather more philosophic than scientific. He considers that the organism in its environment is a unitary process, not a fusion of environmental processes and basic internal processes, as some of the older psychologists have postulated. He emphasizes the fact that the organism tends to draw as much out of the environment as possible into the personality and to project the personality on to the life about it. Most of the ideas in the book are not new. Some psychiatrists may be unaware of the holistic approach to the field, but it is a matter of common knowledge among psychologists that such an approach is in existence although it is not accepted by all psychologists. There is much ecologicistic writing, and the author does not hesitate to use foreign words to express a concept if necessary. The whole picture he presents is a complex one requiring a great deal of background. He makes no contribution to diagnosing and treating patients although the book undoubtedly would aid a psychiatrist doing such work in being critical of himself in applying certain theories to his thinking. It is a work such as this that leads psychiatrists into the stratosphere of semantics rather than to the terra firma of natural science.

Workmen's Compensation and the Physician. A Manual for the Use of General Practitioners and Insurance Carriers. By Henry H. Jordan, M.D. Associate Orthopaedic Surgeon, Lenox Hill Hospital, New York, N. Y. With a discussion of Traumatic Neuroses. By Paul H. Hoch, M.D. Cloth Price \$3.00. Pp. 180. New York, Toronto & London: Oxford University Press, 1941.

The author presents this manual in the hope that it will serve as a guide for the general practitioner of medicine and the insurance carrier in the handling of injuries coming within the purview of workmen's compensation laws. He discusses the relationship of the general practitioner to workmen's compensation cases, devoting attention to methods of examination of industrial injuries and their treatment, explores the difficult question of causal relationships between disability and injury, including aggravation of pre-existing conditions, and includes a chapter on expert opinion and disability evaluation. The concluding chapters present the relationship of physical therapy to industrial injuries, the use of orthopedic appliances and the part that traumatic neuroses assume in the general picture of this particular field of medical practice. The manual embodies material previously published in the *Archives of Physical Therapy, the Medical Record* and *Industrial Medicine*.

Handbook of Hygiene for Students and Practitioners of Medicine. By Joseph W. Bigger, M.D., Sc.D., F.R.C.P., Professor of Bacteriology and Preventive Medicine, University of Dublin, Dublin. Second edition. Cloth Price \$1.00. Pp. 414. Baltimore: William Wood & Company, 1941.

This edition like the first is intended for medical students. The material is presented in a way that might be useful to the physician in general practice, however, and to this end a new chapter on the relation of the physician to the health department has been added. In the brief confines of four hundred pages the author has covered all the communicable diseases together with a chapter on such systemic diseases as cancer, diabetes, heart disease and rheumatism. Then follow chapters on insects and parasitic worms, disinfection, water, food, air and ventilation, waste disposal and sewerage, housing, occupational hygiene, maternity and infant hygiene and personal hygiene. The range is so great that only brief attention can be given each item. The information is succinct and accurate, however, and the book should prove useful for the purpose intended. Statistics that are given are mostly for England and Wales. The chapter on chemical warfare, included in the first edition, has been omitted.

Repairmen Will Get You If You Don't Watch Out. By Roger William Bliss and John Patrie. Cloth Price \$1.00. Pp. 271. Garden City, New York: Doubleday, Doran & Co., Inc., 1942.

This book, dedicated to the *Reader's Digest*, is essentially a reprint of the essays published in that periodical dealing with experiences of actual observers in getting motor cars, radios, watches, typewriters, vacuum cleaners and electric irons repaired. Additional chapters provide some personal letters sent to the authors by readers and also by members of the trades concerned. Apparently repairmen generally resented the techniques of investigation, but some garages took advantage of the series

of articles to indicate that every one does better using his home garage and home radio repairman than he does calling on strangers. A special chapter on doctors and lawyers refers to the investigation of optometry carried on by Rus some years ago and then points out that professional services are quite different from the services of repairmen. The author is convinced that by and large doctors do as well as they can, as idealistically as they can with much more conscience "than our friends in the garages." This book will be of interest to every one who has ever come in contact with the cost of repairs of ordinary devices—and that means everybody.

Health in Schools. Twentieth Yearbook. Cloth Price \$2. Pp. 544. With Illustrations. Washington, D. C.: American Association of School Administrators, A Department of the National Education Association of the United States, 1942.

The special Commission on Health in Schools of the American Association of School Administrators offers in this year book much material that is a guide to standard practice. The preface indicates that the volume is not designed as a piece of propaganda in relationship to social action or extension of the Social Security Act. Health has long been a name of education. This book coordinates and standardizes procedures toward the realization of this aim. There are sections on individual health, mental hygiene, communicable disease, school environment, personnel and legislative problems. The various appendices provide a mass of important bibliographic and other reference material. The year book concludes with a list of members and some excellent indexes.

War, Politics and Emotion. By Geoffrey Bourne. With an introduction by Dorothy Canfield Fisher. Cloth Price \$1.25. Pp. 110. New York: Interlight Publishing Corporation, 1941.

In her introduction to this book Dorothy Canfield Fisher says that "We can hardly have too many good, clear, readable statements of the reasons political, economic, emotional and glandular, why human beings continue to commit the imbecile crime of colliding with each other in war." The author's work is in every sense of the word an appeal to reason. He is convinced that our knowledge of science has outrun our ability to use it intelligently. Dr. Bourne feels that the predominance of aged leaders over youthful ones is one of the chief difficulties of the democracies. In his chapter on democracy, however, he recognizes that it is the highest form of government requiring nevertheless a high standard of intelligence, education and civilization to make it fully effective. The conclusion is that the dominance of men over reason is the cause of all political evils and that such dominance cannot be overcome until politics becomes a science and politicians become qualified in that science.

Handbook of Scientific and Technical Societies and Institutions of the United States and Canada. United States Section Compiled for the National Research Council of the United States by Cattle Hull and Mildred Laddock. Canadian Section Compiled for the National Research Council of Canada by S. J. Cook and P. A. Howard. Bulletin of the National Research Council Number 106. Fourth edition. Cloth Price \$1.00. Pp. 389. Washington, D. C.: National Research Council, National Academy of Sciences, 1942.

A total of 1,269 organizations of the United States and its dependencies is included in this book as well as 143 organizations for Canada. Information under the name of each organization includes the name, address, officers, history, object, membership, meetings and serial publications. Such a directory is obviously invaluable to every one in public work in the scientific field. The National Research Council renders a great service by the development and publication of this book.

Questions in Laboratory Methods. By R. B. H. Cradwohl, M.D., Sc.D., Director, The Grindwohl School of Laboratory Technique, Saint Louis, Mo. Second edition. Paper Price \$2.50. Pp. 71. Saint Louis: Cradwohl School of Laboratory Technique, 1942.

This is a quiz compend on the work of the medical laboratory correlated with the textbook of the same author on "Clinical Laboratory Methods and Diagnosis." Unless one has the latter book, the quiz compend does little but inform the practicing physician of the fact that he knows, after all, very little indeed about the specialty known as clinical pathology. There are many hundreds of questions which will tantalize the mind if one cares to test oneself.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

OPERATING PHYSICIANS' CARS DURING BLACKOUTS

To the Editor—I should like to inquire what a physician would do if required to go out by car during either a practice or a real blackout. Is there equipment for making car lights invisible enough for such purposes? Several of us are interested.

Evelyn G. McLane, M.D. Jackson, Minn.

ANSWER—If physicians are assigned by local defense councils as members of a first aid corps, they may drive during air raids or blackouts if they are in critical areas and their cars are equipped with the Army blackout lighting devices. These devices for emergency and essential vehicles may be procured, after the War Production Board has released sufficient materials for their manufacture, through state or local civilian defense councils. The Office of Civilian Defense has also requested the National Bureau of Standards to investigate the possibility of designing a mask which will be used on cars operating during blackouts. The Bureau of Standards is progressing with the matter and it is hoped that these masks will soon be available to any one who wishes to purchase them. In some areas physicians' cars are marked with a special device developed by the Emergency Medical Service in the Office of Civilian Defense.

TRAUMA PRECIPITATING RHEUMATIC FEVER

To the Editor—In old textbooks one reads that "injuries not infrequently serve to excite rheumatism in the affected joints or in their immediate neighborhood or that a traumatism of the joints can directly change to true articular rheumatism has been observed especially in children." Could you give some information about the clinical course of such cases—whether they differ much from the original rheumatic polyarthritis in their duration and severity (as shown by the erythrocyte sedimentation test), frequent relapses and heart involvement? How does the previous trauma affect the healing of the joints? Does it often take the course of chronic rheumatoid arthritis?

Bendet Nelson, M.D. New York

ANSWER—Acute attacks of rheumatic fever are precipitated most commonly by acute infections of the upper part of the respiratory tract but may be provoked occasionally by trauma. This trauma was regarded as a provocative factor in 5 per cent of almost 800 cases of acute rheumatic fever (Seitz, 1899). Others who have discussed this problem have been Juhlard (1906), Gerbaut and Andermann (1934) and Edstrom (1936). Swift and Cohn (1938), discussing the influence of physiologic trauma on the localization and persistence of rheumatic lesions, noted that while the arthritis of rheumatic fever usually occurs first in the knees and ankles, it more often localizes early in the hands and arms of needleworkers and laundresses. Also noted by Swift and Cohn were cases in which physical trauma in a certain joint preceded the "primary focalization" of rheumatic inflammation in that region; in other cases a bruise apparently induced a relapse in one joint, which was followed later by migratory polyarthritis. Subcutaneous nodules, the prototypes of the proliferative stage of the rheumatic inflammation, occur most frequently in regions subjected to physiologic stress, such as tendons and tendon sheaths as they pass over joints or over structures especially subjected to pressure (for example, the olecranon and the patella). Those valves (mitral and aortic) which are subjected to the most intense physiologic trauma are the ones in which scarring and deformity most frequently occur.

Two series of cases have been reported recently in which trauma initiated exacerbations of rheumatic fever. One series of 12 cases was reported from Australia (*M. J. Australia* 1: 482 [April 6] 1940). In most of these cases there developed soon after trauma an effusion of varying degree which was considered and treated at first as representing traumatic synovitis. But within a few hours to a few days symptoms of acute migratory polyarticular rheumatism developed with or without carditis or erythema marginatum. The time intervals between the trauma and the rheumatic attack varied from four hours to four days but were generally twenty-four to forty-eight hours in duration. In 6 of these 12 cases the attack precipitated by the trauma was the initial rheumatic attack with no previous rheumatic history.

The second series, reported by Glazebrook and Thomson (*Edinburgh M. J.* 48: 674 [Oct] 1941), comprised 11 cases out

of a series of 115 cases of rheumatic fever studied in one institution. Within two to twelve days after various types of injury (sometimes rather trivial) acute rheumatic arthritis affected first the traumatized, later nontraumatized, joints. In some but not all the cases there was also a history of recent tonsillitis or sore throat.

These reports indicate that the rheumatic attacks initiated by trauma resemble in the main those initiated by respiratory infections, that is, acute febrile migratory polyarthritis with no tendency to the production of chronic rheumatoid arthritis in any joint.

MUSCULAR CRAMPS ON EXERTION AND CAISSON DISEASE

To the Editor—Information is requested concerning the end results of caisson disease "bends." A white man aged 29 worked for three years 1933-1938 under compressed air as a tunnel miner, during which time he had three or four attacks of "bends" of the arms and legs lasting eight to ten hours and consisting of severe cramping pains of his muscles which he "walked off." Since then he had had occasional severe cramps on exercise and during the past three or four months had noticed that he walked with a wide base and an extensor thrust and became so tired that he could walk only about a quarter of a mile without the necessity of resting. There was no apparent atrophy or hypertrophy of his muscles; he could do common exercises involving the legs without difficulty and neurologic examination was within normal limits including the Romberg test. Laboratory examination of his blood and spinal fluid yielded normal findings and a negative Wassermann reaction. Could this symptomatology without gross evidence of physical defect be due to old muscle inaction or the "bends"? M.D. Delaware

ANSWER—The late manifestations of caisson disease are associated with injury to the spinal cord resulting in myelitis, monoplegia or paraplegia. The signs are those of spastic paralysis with slight sensory symptoms and bladder dysfunction. This condition is rarely found, for a large number of patients affected with paraplegia in the acute stage recover when treated by decompression. On the other hand, muscle pains ("bends"), air hunger ("chokes"), Meneze's syndrome ("staggers") and the cutaneous symptom ("itch") are not seen, as in this case, years after the acute severe episodes even if there have been repeated attacks. In this instance moreover the "bends" were slight and were "walked off." Silberstein found no cases of joint or limb pains, with enduring disablement in 180 cases examined by him. Other writers also fail to describe "bends" as a residual condition in caisson disease.

It would seem, therefore, that the occasional severe cramps on exercise, the gait disturbance and the fatigue in this case could not be attributed justifiably to the patient's previous occupation. The period of comparative freedom from symptoms followed by exacerbations in the last few months is also suggestive of some other causation, resulting in a progressive disease.

PROCAINE HYDROCHLORIDE WITH AND WITHOUT EPINEPHRINE

To the Editor—I should like some information on local anesthesia in dentistry. I have great difficulty in persuading dental surgeons to inject procaine hydrochloride only. They insist on including a little epinephrine. I have no objection to this except in the presence of heart disease, especially with hypertensive coronary patients who absolutely require dental extractions or other dental work requiring local anesthesia. Why isn't plain procaine hydrochloride just as serviceable for extractions requiring short anesthesia? Of course I realize that the addition of epinephrine prolongs anesthesia or at least I understand that it does. Cannot one get just as good anesthesia by using procaine hydrochloride alone? If not, what is the physiologic or pharmacologic reason? Should not epinephrine be avoided even in small amounts when dealing with the anginal syndrome? M.D., Texas

ANSWER—A local anesthetic is usually combined with epinephrine in dentistry for the purpose of producing a dry field. Procaine hydrochloride will produce just as good anesthesia without epinephrine as with it but does not last quite as long. Epinephrine should be avoided even in small amounts when dealing with the anginal syndrome. The use of epinephrine with the local anesthetic by dentists has become almost routine with many of them, and it is not easy to persuade them to give it up even in the cases in which the physician feels that it would be best if it was omitted. However, there is an increasing number of exodontists who are conscious of the disadvantages of the use of epinephrine and they are omitting it in certain cases or are using cocaine.

NUMBNESS AND TINGLING OF ARMS

To the Editor—A man aged 37, in good health otherwise, has noticed a progressive course of symptoms involving the upper extremities. About one year ago, after prolonged cranking of an outboard motor, he noted soreness and numbness of the right arm. This has persisted and for the past three months has involved also the left arm. An average day's experience is as follows: When he awakens in the morning his hands are swollen and stiff. The hands feel numb. The swelling and stiffness recede but at no time is there strength enough to hold a hammer in the right hand. The strength in the left is unimpaired. On retiring, the right promptly goes to sleep. He may awaken with a sensation like a toothache in both arms and hands especially the right. The symptoms are more aggravated below the elbows. When seen in the evening there are no objective findings. The color is good in all positions. There is no interosseous atrophy and no alteration of reflexes. He is employed as a foreman in the sheet metal division of an automobile radiator plant. There is no lead used on his floor. Paint fumes exist and a process of rustproofing called "bonderizing" has been essentially in his charge for the past two years. He has a sister who responds to cat dandruff with bronchial asthma and a niece who is a cretin dwarf. His basal metabolism rate is within normal limits. The blood picture is normal and the red blood cells are not stippled. There are no evidences of lead poisoning. What etiologic consideration must be given in a case of this nature?

H C Miller M.D. Racine, Wis

ANSWER—The case history suggests either an extramedullary, intramedullary or spinal column lesion in the cervical spinal region. The extramedullary or intramedullary areas may have a tumor or a degenerative or inflammatory disease. The cervical spinal column may be the seat of an arthritis, a tumor or mechanical defect like a ruptured nucleus pulposus or a cervical rib. Certainly a thorough neurologic examination is indicated. Following this anteroposterior and lateral roentgenograms of the cervical spine should be made. If no conclusive information is derived from these examinations the patient should have an accurate manometric study made of his spinal fluid with a total protein determination, a Wassermann test and a colloidal gold test. One must not lose sight of the fact that the patient might have an arthritis in the wrists, elbows or shoulders. From the history given, the latter conclusion appears unlikely.

SPHYGMOMANOMETER AND PAIN SENSITIVITY TEST

To the Editor—Can you give me information regarding one of the pain sensitivity tests? I recently heard of a technic of placing a small sharp object beneath the pressure cuff of a blood pressure manometer and inflating the cuff until the patient could no longer bear the pain.

M D Virginia

ANSWER—Hollander (*J Lab & Clin Med* 24 537 [Feb] 1939) has described a method for the measurement of sensitivity to pain using the simple technic of attaching a piece of roughened metal (such as is used in food graters) to the surface of the blood pressure cuff. Without warning to the patient the cuff is inflated slowly and the pressure reading taken at the moment the patient reveals pain by a verbal protest or wincing. By this means Hollander was able to place patients in three groups: the hypersensitive group who responded below 110 mm of mercury pressure, the hypersensitive group who showed no sensitivity to pain up to 260 mm pressure, and the normally sensitive group who responded between 110 and 260 mm pressure. The technic has been applied by Wilder (*Proc Staff Meet, Mayo Clin* 15 551 [Aug 28] 1940) in an attempt to distinguish pain due to organic disease from that having a functional cause. While the difference is small, on the average patients with functional disease had a significantly greater sensitivity to pain. He also found that the pain threshold was much higher for men than for women.

IRRITATION OF THE SKIN FROM ANESTHETIC OR MASK

To the Editor—A woman received an ether burn to her face during the course of an anesthesia given for an appendectomy. The burns were of second degree nature and consisted of two areas about the size of a quarter (24 mm) on her chin and left cheek. The healed burns have left two erythematous areas which over a period of four months have slowly decreased in size. Since the patient is 19 years of age she is quite sensitive about her appearance. What will the ultimate prognosis as to the clearing of her skin be? Is there any treatment recommended?

M D Massachusetts

ANSWER—Ether vapor rarely irritates the skin of a normal person. However, Duke has reported a case (*J Allergy* 3 495 [July] 1932) exhibiting an allergic response to ether vapor and hypersensitivity when a single drop of liquid ether was placed in contact with the skin. If liquid ether comes in contact with the skin and is prevented from evaporating by some covering, irritation frequently results. Lyons has reported a case of skin irritation of this sort caused by gauze wet with vinyl ether

which was held in contact with the skin of the face (*The Journal*, Oct 1, 1938 p 1284).

The use of anesthetic masks with a rubber cushion has resulted in injuries of the character described in the question. Such injuries may occur in two ways. First undue pressure of the cushion may be exerted on the moist skin of the face by either holding or strapping the mask in place too tightly or from the weight of the head resting in the mask when the patient is in the prone position. If the patient is sensitive to rubber or its constituents, irritation of the skin or a "burn" is more likely to result (Niles, H D. *Dermatitis Due to Rubber Bunion Protector* *The Journal*, Sept 12 1931, p 778). Second rubber may absorb irritant substances and retain them in spite of careful washing. Herwick and Treweek have described a skin injury, of the order referred to in the query, caused by saponated solution of cresol used in sterilizing (*ibid*, Feb 11, 1933 p 407). The face mask had been washed in soap suds and boiled before using and yet the irritant remained in the rubber.

No treatment is likely to hasten the healing process of the injury described. The blemishes referred to as "decreasing in size" will probably disappear completely. Meantime the unsightliness may be mitigated by proper cosmetic aids without delaying the restoration of normal skin.

RECURRENT DISLOCATION OF THE PATELLA

To the Editor—I should like to know the most likely cause of dislocation of the patella (both knees) in a boy of 14 on mild exercise.

George K Herzog M.D. San Francisco

ANSWER—Recurrent dislocation of both patellas is congenital in origin. The first dislocation may not occur until the patient reaches the age of 10 to 14 years. Occasionally however the patellas are dislocated from or before birth. Examination of patients with recurrent dislocation of the patellas will reveal a moderate to marked knock-knee deformity, underdevelopment of the anterior patellar ridge on the lateral condyle of the femur and underdevelopment of the vastus medius muscle. All three of these findings may be factors in producing the instability of the patella. Which of these three factors is cause and which effect has never been definitely determined. If the vastus lateralis is much stronger than is the vastus medius, contraction of the quadriceps muscle may tend to pull the patella over on to the lateral side of the knee joint. This tendency to dislocate is much increased by the presence of a knock-knee deformity and underdevelopment of the patellar ridge on the lateral condyle of the femur.

Congenital absence or underdevelopment of the medial portion of the quadriceps muscle is probably the primary factor leading to the gradual development of knock-knee. The condition can be treated successfully by means of surgery. The insertion of the infrapatellar ligament or the lateral half of this insertion together with a considerable portion of the bone to which it is attached should be transplanted medially and downward on the tibia in order to straighten the line of pull between the origin and the insertion of this muscle. This procedure will prevent further recurrences and permit normal function of the knee.

HISTAMINE DIPHOSPHATE FOR PERIODIC HEADACHES

To the Editor—Can you tell me for what length of time histamine diphosphate is to be used in the treatment of cephalgia and migraine? I have a patient whom I started on an intravenous dose of 275 mg for two days and then 0.275 mg twice weekly for treatment of a persistent cephalgia apparently of a migrainous or an allergic type. She has improved considerably but still has occasional headaches and I don't know whether to continue or discontinue treatment. She has been under treatment for eight weeks.

John J Shea M.D. Coldwater Ohio

ANSWER—Histamine diphosphate (0.275 mg per cubic centimeter) can be given in appropriate amounts subcutaneously for an indefinite period, depending on how well a given patient responds to this type of therapy. As to whether a maintenance dose of this drug is given twice weekly or at more frequent intervals depends entirely on the clinical response of the patient. Some patients require two injections weekly, an occasional patient may require even more frequent injections to prevent recurrence of the headaches and others do not require a maintenance dose at all. No ironclad rule can be stated which will cover all such problems. The average patient who has a vasodilating headache of the histaminic cephalgia type and who responds to this type of therapy usually will require a maintenance dose of histamine twice a week in order to prevent a recurrence of the attacks. Each injection should be below the point of producing any systemic reaction whatever. In view of

the fact that the patient in question seems to have responded well to histamine therapy, it might be well to give an injection every other day instead of twice a week to determine the response to this schedule.

There seems to be a great deal of confusion regarding the type of headache for which histamine therapy is useful. In an article entitled "The Use of Histamine in the Treatment of Specific Types of Headaches," Horton says that histamine "desensitization" is specific for a type of headache which has been described as histaminic cephalgia. This work has been confirmed by Baker at Johns Hopkins University Medical School (The Treatment of Periodic Headache by Injections of Histamine, *Tr Am A Physicians* 55 294, 1940).

In the treatment of periodic headache, one must differentiate clearly between histaminic cephalgia and migraine. Uniformly good results follow histamine therapy when applied to the histaminic cephalgia syndrome, but the authors mentioned do not recommend its use in the treatment of ordinary migraine.

POSSIBLE HYPOPHYSIAL ADENOMA

To the Editor—A white woman aged 21 single has had vomiting for one year, headaches for nine months, weakness for three months and vertigo for three months. The vomiting occurs most commonly right after eating and is worse during any excitement or nervous tension. The headaches are frontal and occipital and more intense in the morning. All her complaints have been worse for three months and two months ago she was forced to give up her work as a secretary. Her menses began at 15 occur at twenty-eight day intervals and last five days. They were somewhat scanty until three months ago when they increased to what would be normal. For six months she has had slight dyspnea on one flight of stairs but no edema. She has fainted several times in the past six months but also fainted several times during the past three years. She is quite tall being 5 feet 11½ inches (181 cm) and she believes that she is still growing. Her three grown brothers are 6 feet 1 inch (185 cm), 6 feet ¼ inch (183 cm) and 5 feet 8 inches (173 cm). Her father is 5 feet 11 inches (180 cm) and her mother is 5 feet 7 inches (170 cm). Her present weight is 126 pounds (57 Kg), her normal weight is 130 pounds (59 Kg). She lost 10 pounds (4.5 Kg) six months ago but lately has been gaining. Physical examination is normal except for prominence of the eyeballs, coated tongue and blood pressure 108 systolic and 70 diastolic. Neurologic examination is negative. Her span is 72½ inches, upper measurement 35 inches, lower measurement 36½ inches. Her fingers and jaw are not above normal size. The urine is normal. The red blood cell count is 4,620,000, the white blood cell count 9,100 with polymorphonuclears 49 per cent, lymphocytes 35 per cent, monocytes 9 per cent, eosinophils 5 per cent and basophils 2 per cent. Barium sulfate roentgenograms of the stomach were normal. Gastric analysis showed free hydrochloric acid 8 degrees, total acid 10 degrees. No occult blood was present and there was a large amount of mucus. Roentgenograms of the skull showed a thinning of the anterior and posterior clinoid processes although the pituitary fossa measured only ½ inch. The visual fields are contracted being 40 degrees at all points in both eyes. The contraction was greater on the temporal side of the left field but not on that of the right field. Testing was done with a 5 mm test object at 33 cm. All colors were equally involved. The vision was 20/25 in each eye corrected by glasses to 20/20. Is there sufficient evidence to diagnose this as a case of pituitary eosinophil adenoma with gigantism? Would roentgen therapy to the pituitary be advisable? Four injections of theelin 10,000 units each at two day intervals for the purpose of inhibiting pituitary gonadotropic secretion did not produce any change. Should this be carried further? Would spinal tap or encephalography be advisable? M D Indiana

ANSWER—Hypophysial adenomas of the eosinophilic type may cause hyperpituitarism, which produces gigantism before puberty and acromegaly after that period. In women one of the earliest symptoms may be the loss of the menses. The basal metabolic rate tends to be elevated, and glycosuria may be present. Other symptoms are bitemporal headaches, a bitemporal hemianopsia due to pressure of the tumor on the optic chiasm, and later optic atrophy. Roentgenologically the hypophysial adenomas present a typical 'ballooned out' expansion of the sella turcica. From the description there does not seem to be enough evidence for the diagnosis of an eosinophilic adenoma. Careful neurologic and visual field examinations should be repeated at regular intervals and the patient should be watched carefully. Dysfunction of the hypophysis may produce similar symptoms except for those of pressure due to an expanding tumor. In cases of hypophysial adenomas roentgen therapy may be followed by edema, and a visual field defect may be produced suddenly. It should be used without surgical removal of the tumor only under careful observation. It is not probable that the injections of theelin will benefit the patient. Artificially inhibiting pituitary functions will not inhibit the growth of an adenoma or decrease its size. A spinal puncture should be done only if one expects to find changes in the cerebrospinal fluid or in its pressure. Encephalography is a neurosurgical procedure, and its indication depends entirely on the neurologic findings. It affords little diagnostic help in tumors of the hypophysis.

DIET AND HAY FEVER

To the Editor—A patient who is a severe sufferer from hay fever and who has been willing to try everything he reads about in the lay press from pituitary extract to Coli Metabolin has heard of a treatment (evidently originating in New York) which is called the No Milk No Carbohydrate Diet. I have used some of these methods, at his suggestions with misgivings and have explained to him the danger of a severe cut in carbohydrates in his diet. I told him I would put him on a 1 to 1 ratio for a ketogenic diet but that if I was to restrict carbohydrates more than to a 1 to 2 carbohydrate fat ratio I would want some authority for doing so. Will you kindly acquaint me with any facts you know regarding this dietary treatment for hay fever? M D Illinois

ANSWER—The use of various diets in the treatment of hay fever and asthma, except such as eliminate allergenic foods, has not proved successful, despite reports to the contrary. Van Leeuwen advised a purine free diet, Adam insisted on avoidance of excessive carbohydrates, and Peshkin and Fineman in 1930 reported good results in asthmatic children from the use of the ketogenic diet. Alexander, however, tried the latter diet in adult asthma and found it of no value. All such diets contain, perforce, portions of an elimination diet, and any improvement may be due to the avoidance of an allergenic food. Osman urged a high carbohydrate diet in asthma, and clinically this advice is supported by the excellent results obtained by this diet plus extra amounts of dextrose.

Search of the literature does not reveal any authentic reports of good results from the dietary treatment of hay fever. It is true, however, that approximately 2 out of 3 patients with hay fever will give positive cutaneous reactions to certain foods or to other substances as well as to the pollens to which they are susceptible. If these other substances or foods are removed from the diet or vicinity, the results obtained by the injection method of treating hay fever are usually improved.

GONADOTROPIC FACTORS OF ANTERIOR PITUITARY

To the Editor—The gonadotropic principles of the anterior pituitary are usually described as being (a) follicle stimulating and (b) luteinizing. Are these principles derived from the pituitary of male animals? Is there direct evidence that there are cyclic changes in the amounts of each principle produced in females corresponding to the cycles of estrus? Do the two factors produce varying responses if injected into men?

H Clair Amstutz M D Goshen Ind

ANSWER—While there is still no absolute proof of the two distinct gonadotropic factors from the anterior pituitary, there is excellent evidence that this is so, and practically pure preparations of each have been isolated. Both the follicle stimulating and the luteinizing factors are present in the glands of both male and female animals although the quantitative amounts may differ somewhat between the male and the female. The amounts of these principles also vary somewhat according to the ovarian cycle in the female but it is most difficult to assay such changes quantitatively. The castrate female or male has a relative preponderance of the follicle stimulating hormone in the pituitary. In the male animal the follicle stimulating hormone acts on the spermatogenic elements of the tubules while the luteinizing hormone stimulates the interstitial cells to secrete androgen, which in turn acts on the secondary sex organs.

METHODS OF SCARLET FEVER IMMUNIZATION

To the Editor—I have avoided immunization with scarlet fever toxin because of the severity of the reactions. Is the ten dose method starting out with 150 skin test units and doubling the dose each time for ten doses as effective as the usual five dose method and can reactions be minimized this way? The total number of units administered is slightly greater if the ten dose method is used being 159,750 compared with 143,150 with the five dose method.

Richard J Steves M D Menomonee, Wis

ANSWER—The ten dose method of immunization against scarlet fever described causes the patient more inconvenience and is not so effective, especially in duration of immunity, as the usual five dose method of immunization. Most unduly severe reactions during the course of immunization against scarlet fever result from deep subcutaneous or intramuscular injection of the toxin. It should be injected just under the skin, so that a visible subcutaneous lump results.

THE ROLL OF THE ROENTGENOLOGIST IN THE DIAGNOSIS OF CONGENITAL CARDIAC LESIONS

CHAIRMAN'S ADDRESS

RALPH S. BROWER, M.D.

BRYAN MAWR 1A

Three methods of examination of the heart are available to the roentgenologist: namely, fluoroscopy, teloradiography and orthodiagraphy. Teloradiography utilizes film exposures at a distance, usually 2 meters, to insure almost parallel rays with the least possible distortion of the cardiac image, orthodiagraphy employs parallel rays in the fluoroscope, and fluoroscopy needs no definition. To these should be added the specialized method of examination by the use of the kymograph, which may be defined as an apparatus consisting of a moving film in contact with a stationary grid having horizontal or vertical slits to permit detailed analysis of cardiac pulsations. Changes in the amplitude and character of pulsations of the various parts of the heart and great vessels can thus be determined, which may be of importance in the diagnosis of pathologic processes involving the heart. The first three methods, or certainly two of them—teloradiography and fluoroscopy—are available to every roentgenologist. The last, the kymograph, is not in general use and is not available to the majority of roentgenologists. Its general clinical value is still debated.

With the advent of cardiology as a specialty, fluoroscopy and orthodiagraphy have gradually become part of the armamentarium of many cardiologists. The roentgenologist should weigh the measures by which he can render himself most useful to the cardiologist or the practitioner in the diagnosis of pathologic cardiac conditions. If shortcomings on his part do exist, they will cause increased dependence of the cardiologist on his own interpretations made from personal fluoroscopic examinations.

It is generally accepted that radiologic examination of the contours of the heart enables the examiner to observe the heart, its size, its position and in many cases its individual chambers. However, accurate diagnosis is dependent on complete clinical as well as roentgenologic findings. A knowledge of the normal roentgenographic image of the heart is most essential not only in the anteroposterior but also in the oblique and lateral projections. Ability to recognize the chambers is a primary requisite. The day when a diagnosis is made from a roentgenogram exposed in the antero-

posterior projection, even though it is a telorontgenogram, should be a thing of the past. Such a practice, if indulged in by roentgenologists, will lead to errors in diagnosis and will bring the practice of roentgenology into disrepute. This is especially true in attempting by such methods the diagnosis of congenital heart lesions. Only the closest collaboration of the roentgenologist with the clinician can insure any accuracy in these conditions, the majority of which are most difficult to diagnose.

Requests are received frequently by roentgenologists for examination of congenital heart lesions in infants and children. The difficulties encountered in such examinations are obvious. These may be listed as lack of cooperation on the part of the patient, difficulty in holding an infant upright for both telorontgenography and fluoroscopy, inability to secure satisfactory exposures in the desired phase of respiration, and the small size of the infant's heart with resultant confusion in identification of the individual chambers. The shadow of the heart may be merged with that cast by an enlarged thymus, with enlarged tracheobronchial and mediastinal lymph nodes, or with the dense areas caused by pulmonary atelectasis or pneumonia. In the fluoroscope it is difficult often to tell whether the pulsation noted in such shadows is transmitted or whether it is the actual pulsating cardiac border. The clinician too has his difficulties and, as Ash states, widely different and entirely unrelated lesions may present similar murmurs or no murmurs may be present. These widely different lesions may cast similar cardiac shadows on the fluoroscopic screen.

Abbott's classification of congenital heart lesions is the one usually quoted. 1 Cyanotic Group. This consists of cases in which no abnormal communication exists between the venous and arterial streams but in which mechanical interference with the circulation caused by the anomaly makes this the seat or point of cardiac strain. Included in this category are left-sided valvular stenoses or insufficiencies, anomalies of semilunar or auriculoventricular cusps, coarctation and hypoplasia of the aorta, primary congenital hypertrophy, congenital rhabdomyoma, pericardial defect, anomalous septums, ectopia cordis abdominalis, congenital arteriovenous aneurysms, and anomalies of the aortic arch and its branches, of the pulmonary artery and of the great venous trunks. 2 Cyanose Tardive. In this group there is arteriovenous shunt with possible temporary or late reversal of flow, while cyanosis is absent except as a transient or terminal phenomenon. These lesions are localized uncomplicated defects of the interauricular, interventricular or aortic septums, patent foramen ovale and ductus arteriosus. 3 Cyanotic Group. These are cases of permanent venous-arterial shunt and right-sided valvular lesions, with or without septal defects.

Lesions such as complete absence of the cardiac or ventricular septums (cor biloculare or triloculare), persistent truncus arteriosus, pulmonary and tricuspid stenosis with closed ventricular septum but patent foramen ovale, pulmonary stenosis with ventricular septal defect and dextraposition of the aorta (tetralogy of Fallot), pulmonary, tricuspid aortic and mitral atre-

shadow to the right of the sternum in the anteroposterior view is most often caused by an enlarged right atrium which gives rise to the appearance of a globular heart situated in the midposition. In infants this picture was more constant in her cases than the one described by Abbott. In only 1 case was there an enlarged right atrium which failed to show demonstrable increase in the cardiac shadow to the right of the sternum in the anteroposterior projection. In that instance a rudimentary left atrium permitted, perhaps, posterior displacement of the enlarged right atrium.

Taussig has shown that in complete transposition of the great trunks the shadow of the aorta and the pulmonary artery at the base of the heart is narrowed in the anteroposterior plane but is definitely broadened in the left oblique diameter where the two vessels become visible, lying more or less parallel to each other. When this is shown fluoroscopically in the presence of persistent cyanosis and with right axis deviation, Helen B. Taussig considers it pathognomonic of transposition of the great vessels. In her experience this anomaly was usually accompanied by hypertrophy of the right ventricle. In the 32 cases of the Children's Hos-

Fig 1—Complete transposition of aorta and pulmonary artery associated with 4 pronounced hypertrophy and dilatation of right atrium and right ventricle hypoplasia of left atrium and left ventricle patent foramen ovale B hypertrophied left ventricle about five times the size of the right enlarged dilated right atrium interventricular septal defect 1.1 cm in diameter

spias, in all of which a ventricular septal defect or patent foramen ovale is present, permitting the circulation to be carried on and giving passage to a permanent venous arterial shunt, transposition or reversed torsion of the arterial trunks, "pure" congenital dextracardia (always complicated by grave cardiac anomalies).

The mere enumeration of these lesions emphasizes the difficulty encountered in attempts at clinical diagnosis, especially when confusing physical signs and symptoms are present, and emphasizes too the necessity of the close collaboration between the roentgenologist and the clinician. In 1939 I had the privilege of studying with Dr. Ash and Dr. Wolman at the Children's Hospital a series of 32 cases of congenital heart disease in infants which came to autopsy. To Dr. Ash I am indebted for the correlation of the autopsy findings with the clinical and roentgenologic data. The series impressed on us the wide variations in the roentgenographic picture in combined lesions in which two or more anomalies were present, as for example pulmonary stenosis in combination with other defects and the similarity of the roentgen picture in two or more different lesions.

Maude E. Abbott states that the characteristic clinical picture of large interauricular septal defects or widely patent foramen ovale with dilated and hypertrophied right chambers has been established by the huge cardiac shadow, occupying chiefly the left side of the thorax with large pulmonary arc and narrow ascending aorta combined with right axis deviation and physical signs absent or indefinite. But in Ash's¹ series of cases she found that an increased width of the cardiac

shadow to the right of the sternum in the anteroposterior view is most often caused by an enlarged right atrium which gives rise to the appearance of a globular heart situated in the midposition. In infants this picture was more constant in her cases than the one described by Abbott. In only 1 case was there an enlarged right atrium which failed to show demonstrable increase in the cardiac shadow to the right of the sternum in the anteroposterior projection. In that instance a rudimentary left atrium permitted, perhaps, posterior displacement of the enlarged right atrium. Taussig has shown that in complete transposition of the great trunks the shadow of the aorta and the pulmonary artery at the base of the heart is narrowed in the anteroposterior plane but is definitely broadened in the left oblique diameter where the two vessels become visible, lying more or less parallel to each other. When this is shown fluoroscopically in the presence of persistent cyanosis and with right axis deviation, Helen B. Taussig considers it pathognomonic of transposition of the great vessels. In her experience this anomaly was usually accompanied by hypertrophy of the right ventricle. In the 32 cases of the Children's Hos-

Fig 2—Pulmonary stenosis A stenosis of the pulmonary valve dilatation of pulmonary artery distal to site of stenosis rounded prominence in region of the pulmonary arc B hypoplasia of conus of right ventricle and of pulmonary artery

As an illustration of the inconstancy of the typical picture described by Taussig, Ash found a narrow mediastinal shadow as noted in roentgenograms associated with transposed vessels in only 25 per cent of the cases of that group. More frequently the tremendously enlarged right auricular appendage projecting upward into the mediastinum caused widening of the mediastinal shadow on the right side. When in association with transposition of the great vessels the left

¹ Ash, Rachel, Wolman, Irving J. and Bromer, Ralph S. Diagnosis of Congenital Cardiac Defects in Infancy. *Am J Dis Child* 58: 8-28 (July) 1939.

ventricle became hypertrophied, there seemed to be a special tendency toward dilatation of the right atrium and auricle.

Enlargement of the conus of the right ventricle is always associated with some degree of fulness in the median or pulmonary arc. This can correctly be diagnosed in some cases as evidence of pulmonary stenosis, as the pulmonary artery, distal to a malformed, contracted ring is often dilated and appears in the roentgenogram as an enlarged pulmonary arc. However, if developmental hypoplasia of the infundibular portion of the right ventricle and pulmonary artery has occurred, a concavity or sharp angulation in the region of the pulmonary arc will be seen. The roentgenographic contour of the stenosed pulmonary artery is thus dependent on the site of the constriction.

Enlargement of the lower left border of the heart is often interpreted as diagnostic of hypertrophy or enlargement of the left ventricle. Pronounced enlargement of this arc is not infrequently caused solely by hypertrophy of the right ventricle. This can be verified by noting anterior bulging of the cardiac shadow in

Pulmonic Stenosis—In Ash's series of 32 cases only 1 case of uncomplicated pulmonary stenosis was found. It occurs much less frequently than patent ductus arteriosus. In uncomplicated stenosis of the pulmonary valve there is not infrequently a dilatation of the pulmonary artery. In this condition the fluoroscope is especially valuable, as the hilar areas should be small in pulmonic stenosis, while in patent ductus arteriosus, which may be confused with it clinically, prominent pulsating shadows are often noted.

Etymology of Fallot—A more frequent lesion is that of pulmonary stenosis in association with dextraposition of the aorta, hypertrophy of the right ventricle and patent interventricular septum. As previously mentioned, the roentgen appearance varies with the site of the lesion, thus if the usual hypoplasia of the conus of the right ventricle and of the pulmonary artery occurs, a concavity or a sharp angulation may be present in the region of the pulmonary arc. However, if stenosis solely of the valve is present there will usually be noted an enlarged pulmonary arc. Lateral and oblique projections will demonstrate the enlargement of the

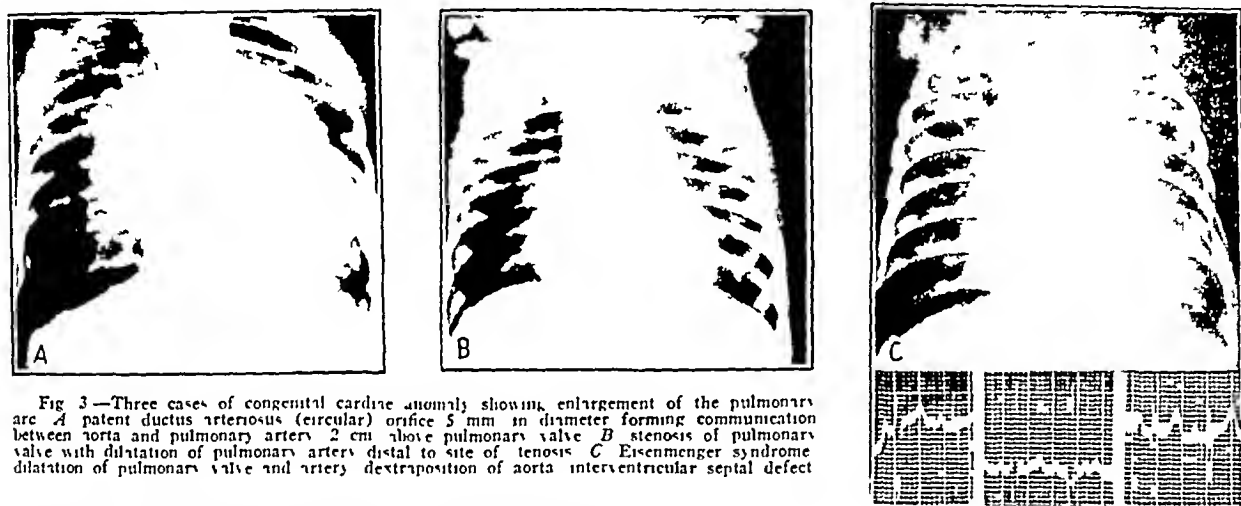

Fig. 3—Three cases of congenital cardiac anomaly showing enlargement of the pulmonary arc. A patent ductus arteriosus (circular) orifice 5 mm in diameter forming communication between aorta and pulmonary artery 2 cm above pulmonary valve. B stenosis of pulmonary valve with dilatation of pulmonary artery distal to site of stenosis. C Eisenmenger syndrome dilatation of pulmonary valve and artery, dextraposition of aorta, interventricular septal defect.

the lateral and oblique projections, with no posterior enlargement of the cardiac shadow. Atrophy of the left ventricle may be shown by flattening of the posterior outline of the heart with increase in the clear space between the heart and the chest wall.

The roentgenographic features of the more usual cardiac defects of which a diagnosis is possible in infancy are as follows (none of these can however, be regarded as pathognomonic and none permit a definite diagnosis from the roentgenographic findings alone).

Intraventricular Septal Defect (maladie de Roger)

—The roentgen contour of the heart is usually unchanged. If the defect is large enough to cause hypertrophy of both the right and left ventricles, these changes can sometimes be demonstrated in the lateral and oblique views. Occasionally enlargement of the pulmonary arc is seen, but this is usually in older children rather than in the infant. No roentgen picture exists which can be considered typical of this defect.

Interauricular Septal Defect—The picture of this lesion as described by Abbott has been mentioned previously. Again it should be emphasized that Ash found the globular shaped heart was more characteristic in infants than the left-sided preponderance of the cardiac shadow described by Abbott.

right ventricle, and the mediastinal shadow is often enlarged to the right side. If the hypertrophy of the right ventricle is sufficiently well defined, the lower pole of the cardiac apex is formed by the right ventricle, the left being displaced upward. This causes the apex of the heart to have a blunted, sometimes straight, appearance, giving rise to the outline called the "cœur en sabot." Sometimes a double apex is described in these cases, the upper being formed by the elevated left ventricular apex and the lower by the right ventricle situated just above the diaphragm shadow.

Complete Transposition of the Great Vessels—This lesion may be associated with either a large right ventricle or a large left ventricle. In the fluoroscopic examination the mediastinal shadow may be narrow in the anteroposterior view but should broaden in the lateral and oblique views.

Patent Ductus Arteriosus—Because of possible relief of symptoms of this lesion by operative procedure there is now even greater necessity for painstaking and careful study to arrive at a correct preoperative diagnosis. The roentgen appearance depends on the size of the arteriovenous shunt. The heart is sometimes normal in size or may show slight generalized enlargement

Enlargement of the right ventricle as well as the left may be demonstrated, and occasionally pronounced prominence of the conus of the right ventricle can be seen, associated in many cases with increased pulsation of the pulmonary artery and its branches in the hilar region. Because of the shunt, increased pressure is exerted in the pulmonary artery and its branches and, if sufficiently large, will cause them to undergo various degrees of dilatation.

The difficulties in the diagnosis of congenital heart lesions in children and especially in infants need not be stressed by quoting percentages of correct clinical diagnoses of various writers. What role should the roentgenologist play in the diagnosis of these lesions?

1 He must make use of the facilities he possesses to the greatest advantageous degree. In older children the examination in the erect position, if clinical conditions permit, can be obtained through cooperation on the part of the patient. A holding apparatus for infants and smaller children can be built at comparatively small expense. If no holder is available for examination in the erect position, a teleroentgenogram can be secured by placing the patient on the floor and by raising the tube to the top of the tube stand. While this position is not as accurate as the erect, it does have the advantage of exposure of the patient in the same position in which the pediatrician usually makes the clinical examination of the heart in infants. Changes in fluoroscopic apparatus for orthodiagraphy often cannot be made by the roentgenologist, but the teleroentgenogram can be used instead to supplement the fluoroscopic observations.

2 In office practice these simpler measures are always available. The fluoroscopic examination in company with the referring cardiologist or pediatrician is most desirable. If they can rely on the roentgenologist's knowledge of the roentgen anatomy of the heart and can accept his recognition of the individual chambers and variations in pulsation, and if the roentgenologist can supplement this with a knowledge of the clinical characteristics of the various lesions, he will hold the esteem of the referring physician. However, if he attempts to diagnose the type of lesion present by an anteroposterior teleroentgenogram alone his frequent errors in diagnosis will soon detract from his reputation with consequences that such loss entails.

3 If the roentgenologist holds a hospital position he should attempt to attend postmortem examinations in all cardiac cases, should see the heart in situ when exposed on the autopsy table and should correlate the appearance of the heart and the size and shape of the chambers with his roentgenographic findings and thus learn from his personal observations the pathologic changes which have caused the abnormal contour of the heart.

CONCLUSION

With the recognition of his proper sphere in the diagnosis of congenital cardiac lesions and with his constant endeavor to perfect his knowledge of the roentgen anatomy of the heart, the roentgenologist will maintain his status as a consultant of value and diagnostic worth and will not see himself displaced by the cardiologist. He will maintain his position as he has maintained it in the practice of urology, gastroenterology and the other specialties.

Bryn Mawr Hospital

DIGESTIVE DISEASE AND MILITARY SERVICE

WITH SPECIAL REFERENCE TO THE MEDICAL
DEPARTMENT OF THE U S ARMY

JOHN L KANTOR, MD

Colonel Medical Reserve U S Army

NEW YORK

DIGESTIVE DISEASE IN PEACE

The role played by digestive disease in military service has always been important. In our peacetime army this is clearly evident from the accurate statistics set forth in the Annual Reports of the Surgeon General. The latest available report,¹ issued June 30 1941, covers the calendar year 1940 and is typical of the experience of the past decade. Diseases of the digestive system ranked third as a cause for admission to sick report, the rate being 137 per thousand strength (chart 1), they ranked fourth as a cause of death the rate being 0.20 per thousand strength (chart 2), causing 27 per cent of all deaths from disease, they ranked fifth as a cause of discharge for disability the rate being 1.09 per thousand (chart 3), they ranked third as a cause of loss of time the average daily noneffective rate per thousand strength being 3.93 (chart 4).

Digestive diseases occurring in the Army are in general similar to those encountered in civil life. It is interesting to note that the incidence of duodenal ulcer has increased in the army population as it has in the civilian. Perhaps the most striking statistics of the increase of this disease among civilians are those published from the Bellevue Hospital in New York by Hinton,² who showed that from 1910 to 1931 the percentage of ulcers to total admissions rose from 0.09 to 0.77, almost a ninefold increase in twenty-one years. The experience of the Army is similar. In 1930 the admission rate for ulcer of the duodenum was 1.1, in 1938 it was 1.4 and in 1939 1.6 an increase of 50 per cent in almost a decade. In 1940, although the admission rate dropped below 1.6 duodenal ulcer led all other digestive conditions as a cause for discharge.

DIGESTIVE DISEASE IN WAR

Intestinal Disorders—The history of typhoid and dysentery has been told before.³ In fact, the striking reduction of typhoid and paratyphoid fever after the introduction of compulsory typhoid vaccination in 1911 is one of the glories of the medical department of the U S Army (chart 5). During the first world war the admission rate for dysentery in the American Army in the United States and Europe was only 1.06 and the death rate 0.02,⁴ but this was probably due chiefly to favorable environment, for the British, during the Dardanelles campaign, reported an admission rate for dysentery (including diarrhea, colitis and enteritis)

Released for publication by the War Department Manuscript Board which assumes no responsibility other than censorship for the content of this article.

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Third Annual Session of the American Medical Association Atlantic City N. J. June 11 1942.

Owing to lack of space this article has been abbreviated for publication in THE JOURNAL by the omission of the charts and some reading matter. The complete article appears in the author's reprints.

of 25394, with a death rate of 6.93 per thousand.⁵ Figures are not yet available from the present war effort on our part, but during the 1940 maneuvers of the First Army in upper New York State I⁶ reported 283 cases of gastroenterocolitis and 40 of bacillary dysentery in a total of some 557 medical admissions to the First Evacuation Hospital, representing, on the basis of 88,000 troops for one month a rate of 38.5 for the former and 5.5 for the latter disease. Similarly, during the June 1941 maneuvers of the Twenty-Seventh Division in Tennessee, Colonel Salisbury⁷ reported an admission rate of 271 for diarrhea. One may expect an increase over these figures under the unfavorable conditions of war in foreign lands, and particularly so in the tropics.

Reports on digestive disease encountered in the present war are now becoming available. These originate almost entirely from foreign sources. Diarrheal disorders have been discussed chiefly by German writers. Dysentery affected the German army in the Polish campaign of 1939. Steuer⁸ reports that from mid-September to mid-December 1,200 cases were under treatment in a base hospital set aside for contagious diseases. There were 40 deaths, representing a mortality of 3.3 per cent.

The treatment of diarrheal disorders in the field has been described both in general⁹ and with special reference to service in the tropics.¹⁰ In a comprehensive paper describing the medical conditions now facing our troops in the West Indies, Saunders¹¹ has stressed the importance not only of typhoid, dysentery and sprue but of food poisoning in particular.

Peptic Ulcer—Here again one must rely, so far at least, on foreign experience. The British have reported a high incidence of ulcer disease both in troops evacuated from France in the early part of the war¹² and in those stationed in Great Britain.¹³ The incidence of ulcer varies from 35 to 55 per cent of the gastrointestinal cases.

The Canadians have also reported a high incidence of ulcer disease.¹⁴ In Germany an interesting study has been made on ammunition workers of the Krupp factories. Rothe¹⁵ reviewed 7,488 gastric x-ray studies on workers and their families during the three years between Nov. 1, 1937 and Oct. 30, 1940 and observed an increase in the total number of examinations from year to year as well as a relative increase of positive findings. Among these findings, duodenal ulcers were the most common. Beginning with September 1939—the first war month—the number of duodenal ulcer scars increased.

An interesting study of the incidence of ulcer perforation during heavy air raids is reported by Stewart and Winsor.¹⁶ Investigation of the perforation rate in London from January 1937 to August 1940 showed that the monthly average was 23. In September and October 1940 (heavy air raid periods), the monthly average rose to 64. The ratio of gastric to duodenal perforation was 1.6:1. The authors suggest that anxiety is a possible cause for the increase in ulcer perforation.

Neurosis—Digestive neurosis, meaning functional disorders without evidence of organic disease, were encountered by me¹⁷ in a little more than one third of the cases of dyspepsia seen in the gastrointestinal service of U. S. Army General Hospital 14 at Fort Oglethorpe, Ga., during the first world war. Lieutenant Colonel Frust¹⁸ reports that between 18 and 20 per cent of all patients admitted to the gastrointestinal and metabolic section of the Fitzsimons General Hospital in Denver during the present emergency eventually turn out to have neuroses of some type or some constitutional psychopathic state.

Graham and Kerr¹⁹ reported from a single military hospital in Northwest Britain that 24 per cent of the gastrointestinal cases were functional in nature, and on reviewing 2,500 dyspeptic patients admitted to several military hospitals in various parts of Great Britain Tidy found that such cases constituted 35 per cent of the total. It is very likely that the functional cases (neuroses) originate in civil life and occur in similar proportion in the army. Psychologic factors in the army are not generally considered very important. It is true that there is some worry over business and separation from family, but this is probably balanced by relief from insecurity of occupation²⁰ or from unhappy home or work surroundings.²¹

Gastritis—The incidence of gastritis in military service is as yet undetermined. Unless the gastroscope is employed and the findings are correlated with the clinical picture, it may be quite impossible to distinguish between functional disorders and gastritis. Several English authors use the term "gastritis" to cover all dyspepsias in which an organic lesion is not demonstrated, which is, to say the least confusing, although an editorial in the *Lancet*²² quite properly points out that "gastritis can only be confidently excluded by endoscopy, a point of some importance in the investigation of the large number of cases of dyspepsia now occurring in service personnel."

Reporting from a Swiss military hospital during the present war mobilization, Haemmerli²³ claims that of 260 dyspeptic patients 43 per cent suffered from "gastritis" and only 10 per cent from "nervous dyspepsia." It is, however, difficult to understand on what basis he makes such a precise distinction, as nowhere does he mention the use of the gastroscope.

Basing his opinion largely on experience with German war veterans after the first world war, Schindler²³

believes that chronic gastritis is probably rare in recruits but is very likely to develop in soldiers after one or two years of active field service chiefly as a result of ingesting poor food and contaminated water. He further believes that, once this disease is established the soldier is no longer fit for active duty. Hurst,²⁴ on the other hand thinks that patients with gastritis can probably be treated in army hospitals with sufficient success to return in three or four weeks to full duty on an ordinary diet.

In our own military hospitals gastroscopy has been practiced since at least 1937. One experienced observer²⁵ reports that in 1940, a peace year, 87 per cent of the cases admitted to the gastrointestinal section of a general hospital showed gastroscopic evidence of chronic gastritis. The present emergency offers a splendid opportunity for gastroscopic studies of great practical value.

Malingering—The incidence of malingering in relation to gastrointestinal disorders has not been high during the present war according to British sources. This is possibly related to the availability of improved and impressive methods of objective diagnosis such as roentgenoscopy and gastroscopy. Schindler found many cases of gastritis among German war veterans of the first world war who had been suspected of malingering. In an interesting study of this subject Hulett²⁶ points out that "in any case of painless persistent afebrile diarrhea, without discoverable evidence as to its nature malingering should be suspected."

PROPHYLAXIS OF DIGESTIVE DISEASE IN THE U S ARMY

From the military point of view prophylaxis of digestive diseases can be effected by the exclusion of dyspeptic patients from army service by immunization against certain infectious diseases of the digestive system, by the supervision of food supplies and by the enforcement of general sanitary measures.

Recruiting Policies—Exclusion of dyspeptic patients is accomplished by appropriate recruiting policies. Standards of physical examination during mobilization have been published by the War Department (Mobilization Regulations No 1-9, Aug 31, 1940). These govern the procedure of the examining physicians on Selective Service ("draft") boards as well as those on Army induction boards. To the disqualifying digestive conditions, such as peptic ulcer, listed therein should be added ulcerative colitis and regional ileitis which are diseases of youth and, where older age groups are concerned, neoplasms. Functional digestive disorders are not considered a cause of rejection. Most authorities agree that soldiers with ulcers are unfit for active duty²⁷ and that in the great majority of cases (80 to 90 per cent) the ulcer existed prior to enlistment.

In contrast to this view is the view of a German writer²⁸ who believes that even old callous ulcers can be cured and that no one should be declared permanently unfit for military service until serious attempts

at treatment have failed adding that the danger of recurrent ulcer or life threatening hemorrhage is not greater during exercise than if the patient is kept away from work.

Swiss army doctors²⁹ apparently feel that soldiers (enlisted men) with healed ulcers can be utilized provided they are assigned to "diet companies" or to stations in which special diets can be carried out. Practically all writers agree that officers with healed ulcers can render useful army service.

The present policy in the U S Army regarding the acceptance of candidates who have or have had peptic ulcer is stated by General C C Hillman,³⁰ chief of the Professional Services Division of the Surgeon General's Office as follows:

In view of the fact that officers are generally able to look after their diet somewhat better than enlisted men it is the policy of this office to accept for limited service [italics mine] applicants for commission who have histories of gastric or duodenal ulcer, provided such histories indicate freedom from activity during the preceding five years and provided further that gastrointestinal x-ray at the time of examination is negative.

For enlisted service the presence of an ulcer or a trustworthy history of one at any time in the past is considered disqualifying. Because of the usual habits of soldiers and their inability to give themselves appropriate dietetic care in military messes it has been the custom during times of peace to discharge soldiers when a definite diagnosis of peptic ulcer has been made. I doubt that such a strict rule will hold at the present time that is, so far as the discharge of those who under proper treatment appear to recover is concerned.

What modifications in this policy may undergo in the case of a long drawn out war requiring the utilization of our total man power remains to be seen.

One may now ask how effective are the existing physical examinations in excluding undesirable candidates with digestive disorders particularly those with ulcer from admission to our rapidly expanding army. This is a matter of great practical importance, since even if ulcer is universally granted to be a non-service connected disability, previous experience has shown how difficult it is for our people to resist the generous interpretation that no matter how little they may have contributed in actual service, soldiers so afflicted will deserve compensation as veterans on the ground that their condition had been aggravated while in the army. These physical examinations as far as selectees are concerned were originally performed by "draft board" physicians at the beginning of our mobilization effort and are now being conducted by induction boards under stricter and more uniform army supervision. At first the investigation was based chiefly on the history and physical examination but soon the War Department authorized, in doubtful cases, the admission to a military or other federal hospital for a period not exceeding three days of any selectee for the purpose of more complete diagnostic study. With this last important addition, the procedure is similar to that suggested by me ten years ago and published in the *Military Surgeon* in 1934.³¹

Some idea of the success of this plan can be gained from two preliminary reports recently made available. The first is that issued by the Selective Service Sys-

tem³ on Nov 10 1941 and supplies data from a sample of 19,923 registrants between the ages of 21 and 38 inclusive who had been examined in Selective Service local boards. Defects of abdominal viscera showed a rate of 12.2 per thousand examined including a rate of 4.4 per thousand for peptic ulcer. Hemorrhoids gave an additional rate of 30.6 per thousand. The second report was made available on Feb 23 1942 through Col John W Meehan³³ chief of the statistics division of the Surgeon General's Office. The figures are based on a sample of 30,436 class 4 rejections by army induction boards. In this group there were 167 rejections for peptic ulcer and an additional 11 for a history of gastroenterostomy. Expressing the rate for ulcer on the basis used by the Selective Service System, one finds that rejections for this disease represent a rate of 5.5 per thousand.

For purposes of orientation and appraisal, these sets of figures may best be compared with the experience of insurance companies and that of the peacetime army hospital admission rate mentioned earlier in this paper. According to Dr Louis I Dublin,³⁴ statistician to the Metropolitan Life Insurance Company, only 1 male in 1,000 under 35 years of age gives a history of peptic ulcer. Hence one may conclude that the present army procedure is from four to five times as effective in revealing ulcer as is the familiar life insurance examination based almost entirely on the history alone. Comparison with the peacetime military hospital admission rate is equally interesting, since the Selective Service examination reveals an incidence rate (4.4) about two and one-half times as high as the hospital admission rate (1.6), and the Army induction board examination shows a rate (5.5) almost three and one-half times as great.

Immunization in the Control of Intestinal Infections—With the spread of the war to tropical climes, our military personnel will become more and more exposed to indigenous infections and infestations affecting the digestive system. It must be recalled, however, that ever since Spanish War and Philippine Insurrection days our medical department has been interested in this field and already has to its credit some important achievements. The first of these is the demonstration that typhoid can be stamped out of modern armies by preventive vaccination. In the Spanish War the annual admission rate for typhoid and paratyphoid fever was 150 per thousand strength. In 1909, when vaccination was made voluntary, it dropped to 3 and after the prophylaxis was made compulsory in 1911 it practically disappeared. In 1899 Ashford discovered that Puerto Rican anemia was due to ancylostoma. This led to a widespread anti-hookworm campaign in our own Southern states, generously supported in its early phases by the Rockefeller Foundation. During the first world war, extensive surveys were made in our Southern camps with the result that large numbers of troops were disinfested and knowledge of applied sanitation was further disseminated in many Southern communities.

At the beginning of the year 1942 the War Department³⁵ ordered that all military personnel stationed in or traveling through Asia or other regions in which

cholera is known to be present in endemic or epidemic form shall be immunized with cholera vaccine. The vaccine now approved consists of a suspension of 8,000 million killed cholera vibrios per cubic centimeter. Initial vaccination consists of two subcutaneous injections with an interval of from seven to ten days between the injections. The first dose is 0.5 cc and the second 1 cc of the vaccine. Since the immunity so obtained is not permanent, it may be necessary to administer subsequent injections of 1 cc doses every four to six months as long as danger of infection is present.

Prevention of Intestinal Diseases by Nonspecific Measures—Immunization by preventive inoculation is still lacking for the common diarrheas for food infections by the salmonella, paratyphoid B, hog cholera group of bacilli, for food intoxication or botulism, for bacillary and protozoal dysenteries and for helminthic infections.

Food infection is important largely because of its disabling effect on a military organization. As all members of a company are fed at one mess, the entire unit may be exposed to infection at one time. The resulting epidemic is explosive in nature and may interfere seriously with military activities at a critical moment.³⁶ In active operations dysentery, especially the bacillary variety, is extremely dangerous, as it spreads most rapidly under combat conditions when disease control is least effective.

The prophylaxis against all the aforementioned diseases lies in attention to diet, mess hygiene and general sanitation. The army has in operation an extensive system of food inspection. It is the duty of the Veterinary Corps not only to inspect meat and dairy foods at both their source and their issue but also to investigate the sanitary condition of all establishments manufacturing, handling, storing or transporting such materials (Army Regulations 40-2005). On the other hand, the Medical Corps is responsible for the general supervision of foods, kitchens, mess halls, bakeries and exchanges (Army Regulations 40-270) as well as the active treatment of communicable intestinal diseases, the control of carriers and the examination of food handlers (Army Regulations 40-205, Army Regulations 40-225). General sanitary measures include, in addition to the supervision of foods, the control of water supplies, personal hygiene, the elimination of flies, the disposal of human excreta and the isolation of patients.

ORGANIZATION OF THE MEDICAL DEPARTMENT FOR THE MANAGEMENT OF DIGESTIVE DISEASES

Field and Hospital Service—The organization of the medical department of the Army for the treatment of digestive diseases may be considered under two heads: (a) in the field and (b) in fixed hospitals. Medical work in the field is carried out by medical personnel attached to troops, by medical battalions or regiments in hospital clearing stations, in army medical laboratories or in mobile evacuation hospitals. The officers assigned to such organizations are military surgeons trained in the application of the sanitary measures previously mentioned, in the treatment of mild and temporary disabilities, in the recognition of malingering and particularly in the selection of appropriate cases for evacuation to the rear.

It is in the fixed hospitals of the communications zone and of the zone of the interior that special gastroenterologic personnel and services first become available. Perhaps a brief summary of the development of gastroenterology as an army specialty may be in order at this point.

The first attempt in this direction was made in the summer of 1917, when a committee from the Section on Gastro-Enterology and Proctology of the American Medical Association, consisting of Drs. Martin Rehfuess, chairman, Dudley Roberts, D. N. Murray, W. M. Beach and others, suggested to Surgeon General Gorgas that gastroenterology should be represented in medicomilitary practice. As a result of several conferences a section of gastroenterology was created in the division of internal medicine in the Surgeon General's Office under the direction of Major Seale Harris.³⁷ This took place in October 1917 and was soon followed by the assignment of gastroenterologists to many of the thirty-three base hospitals in this country. Although the section of the Surgeon General's Office was discontinued in 1918, several gastrointestinal wards were actually established and operated in base hospitals until the end of the war. Furthermore, the idea itself was perpetuated in that all the large permanent army general hospitals to which general medical cases are admitted now operate sections of gastroenterology as an integral part of their medical services. Following the war there was a reaction against overspecialization in some quarters, but this was effectively controlled by the far sighted attitude of Major General Charles R. Reynolds,³⁸ who, as surgeon of the Second Corps Area and later as Surgeon General of the Army, vigorously supported and encouraged the policy of the intelligent utilization of specialists throughout the medicomilitary establishment. When the time came for the organization of the new cantonment type mobilization plan general hospital, a section of gastroenterology was included in the official table of organization (T/O 8-507, July 25, 1940). This section is one of the six comprising the medical service, the other five being neuropsychiatry, general medicine, cardiovascular, communicable diseases and (sick) officers. As at present organized, the section of gastroenterology is in charge of a major in the Medical Corps as chief, with one or two assistants who may be captains or lieutenants. Finally, on Dec. 15, 1940 a gastroenterologist was authorized as a member of the medical service of station hospitals of eight hundred bed capacity or over.
